ATM Case Study, Part 2: Implementing an Object-Oriented Design

26

To generalize means to think.
—Georg Wilhelm Friedrich Hegel

Objectives

In this chapter you'll:

- Incorporate inheritance into the design of the ATM.

- Incorporate polymorphism into the design of the ATM.

- Fully implement in C++ the UML-based object-oriented design of the ATM software.

- Study a detailed code walkthrough of the ATM software system that explains the implementation issues.

26.1 Introduction

In Chapter 25, we developed an object-oriented design for our ATM system. We now begin implementing our object-oriented design in C++. In Section 26.2, we show how to convert class diagrams to C++ code. In Section 26.3, we tune the design with inheritance and polymorphism. Then we present a full C++ code implementation of the ATM software in Section 26.4. The code is carefully commented and the discussions of the implementation are thorough and precise. Studying this application provides the opportunity for you to see a more substantial application of the kind you're likely to encounter in industry.

26.2 Starting to Program the Classes of the ATM System

[*Note:* **This section can be studied after Chapter 9.**]

Visibility

We now apply access specifiers to the members of our classes. Access specifiers public and private determine the **visibility** or accessibility of an object's attributes and operations to other objects. Before we can begin implementing our design, we must consider which attributes and operations of our classes should be public and which should be private.

Previously, we observed that data members normally should be private and that member functions invoked by clients of a given class should be public. Member functions that are called only by other member functions of the class as "utility functions," however, normally should be private. The UML employs **visibility markers** for modeling the visibility of attributes and operations. Public visibility is indicated by placing a plus sign (+) before an operation or an attribute; a minus sign (–) indicates private visibility. Figure 26.1 shows our updated class diagram with visibility markers included. [*Note:* We do not include any operation parameters in Fig. 26.1. This is perfectly normal. Adding visibility markers does not affect the parameters already modeled in the class diagrams of Figs. 25.18–25.21.]

Navigability

Before we begin implementing our design in C++, we introduce an additional UML notation. The class diagram in Fig. 26.2 further refines the relationships among classes in the ATM system by adding navigability arrows to the association lines. **Navigability arrows** (represented as arrows with stick arrowheads in the class diagram) indicate in which direction an association can be traversed and are based on the collaborations modeled in communica-

tion and sequence diagrams (see Section 25.8). When implementing a system designed using the UML, you use navigability arrows to help determine which objects need references or pointers to other objects. For example, the navigability arrow pointing from class ATM to class BankDatabase indicates that we can navigate from the former to the latter, thereby enabling the ATM to invoke the BankDatabase's operations. However, since Fig. 26.2 does not contain a navigability arrow pointing from class BankDatabase to class ATM, the BankDatabase cannot access the ATM's operations. Associations in a class diagram that have navigability arrows at both ends or do not have navigability arrows at all indicate **bidirectional navigability**—navigation can proceed in either direction across the association.

Like the class diagram of Fig. 25.10, the class diagram of Fig. 26.2 omits classes BalanceInquiry and Deposit to keep the diagram simple. The navigability of the associations in which these classes participate closely parallels the navigability of class Withdrawal's associations. Recall from Section 25.4 that BalanceInquiry has an association with class Screen. We can navigate from class BalanceInquiry to class Screen along this association, but we cannot navigate from class Screen to class BalanceInquiry. Thus, if we were to
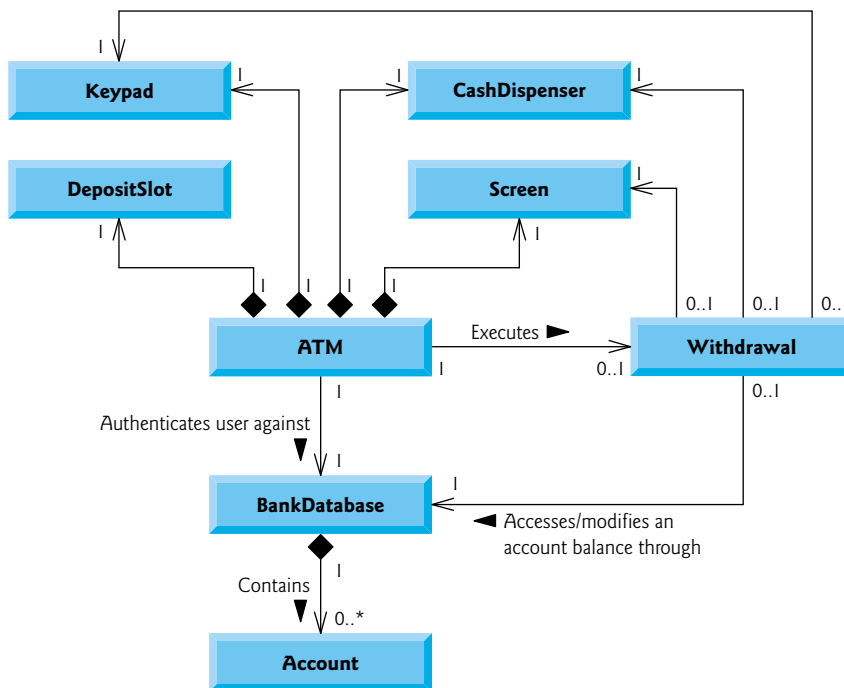

Fig. 26.2 | Class diagram with navigability arrows.

model class `BalanceInquiry` in Fig. 26.2, we would place a navigability arrow at class `Screen`'s end of this association. Also recall that class `Deposit` associates with classes `Screen`, `Keypad` and `DepositSlot`. We can navigate from class `Deposit` to each of these classes, but not vice versa. We therefore would place navigability arrows at the `Screen`, `Keypad` and `DepositSlot` ends of these associations. [*Note:* We model these additional classes and associations in our final class diagram in Section 26.3, after we have simplified the structure of our system by incorporating the object-oriented concept of inheritance.]

Implementing the ATM System from Its UML Design
We are now ready to begin implementing the ATM system. We first convert the classes in the diagrams of Fig. 26.1 and Fig. 26.2 into C++ header files. This code will represent the "skeleton" of the system. In Section 26.3, we modify the header files to incorporate the object-oriented concept of inheritance. In Section 26.4, we present the complete working C++ code for our model.

As an example, we begin to develop the header file for class `Withdrawal` from our design of class `Withdrawal` in Fig. 26.1. We use this figure to determine the attributes and operations of the class. We use the UML model in Fig. 26.2 to determine the associations among classes. We follow the following five guidelines for each class:

1. Use the name in the first compartment of a class in a class diagram to define the class in a header file (Fig. 26.3). Use `#ifndef`, `#define` and `#endif` preprocessor directives to prevent the header from being included more than once in a program.

```
1   // Fig. 26.3: Withdrawal.h
2   // Definition of class Withdrawal that represents a withdrawal transaction
3   #ifndef WITHDRAWAL_H
4   #define WITHDRAWAL_H
5
6   class Withdrawal
7   {
8   }; // end class Withdrawal
9
10  #endif // WITHDRAWAL_H
```

Fig. 26.3 | Definition of class `Withdrawal` enclosed in preprocessor wrappers.

2. Use the attributes located in the class's second compartment to declare the data members. For example, the `private` attributes `accountNumber` and `amount` of class `Withdrawal` yield the code in Fig. 26.4.

```
1   // Fig. 26.4: Withdrawal.h
2   // Definition of class Withdrawal that represents a withdrawal transaction
3   #ifndef WITHDRAWAL_H
4   #define WITHDRAWAL_H
5
6   class Withdrawal
7   {
8   private:
9      // attributes
10     int accountNumber; // account to withdraw funds from
11     double amount; // amount to withdraw
12  }; // end class Withdrawal
13
14  #endif // WITHDRAWAL_H
```

Fig. 26.4 | Adding attributes to the `Withdrawal` class header file.

3. Use the associations described in the class diagram to declare references (or pointers, where appropriate) to other objects. For example, according to Fig. 26.2, `Withdrawal` can access one object of class `Screen`, one object of class `Keypad`, one object of class `CashDispenser` and one object of class `BankDatabase`. Class `Withdrawal` must maintain handles on these objects to send messages to them, so lines 19–22 of Fig. 26.5 declare four references as `private` data members. In the implementation of class `Withdrawal` in Section 26.4, a constructor initializes these data members with references to actual objects. Lines 6–9 #include the header files containing the definitions of classes `Screen`, `Keypad`, `CashDispenser` and `BankDatabase` so that we can declare references to objects of these classes in lines 19–22.

4. It turns out that including the header files for classes `Screen`, `Keypad`, `CashDispenser` and `BankDatabase` in Fig. 26.5 does more than is necessary. Class `Withdrawal` contains *references* to objects of these classes—it does not contain actual objects—and the amount of information required by the compiler to create a reference differs from that which is required to create an object. Recall that creating an object requires that you provide the compiler with a definition of the class that

```
 1   // Fig. 26.5: Withdrawal.h
 2   // Definition of class Withdrawal that represents a withdrawal transaction
 3   #ifndef WITHDRAWAL_H
 4   #define WITHDRAWAL_H
 5
 6   #include "Screen.h" // include definition of class Screen
 7   #include "Keypad.h" // include definition of class Keypad
 8   #include "CashDispenser.h" // include definition of class CashDispenser
 9   #include "BankDatabase.h" // include definition of class BankDatabase
10
11   class Withdrawal
12   {
13   private:
14      // attributes
15      int accountNumber; // account to withdraw funds from
16      double amount; // amount to withdraw
17
18      // references to associated objects
19      Screen &screen; // reference to ATM's screen
20      Keypad &keypad; // reference to ATM's keypad
21      CashDispenser &cashDispenser; // reference to ATM's cash dispenser
22      BankDatabase &bankDatabase; // reference to the account info database
23   }; // end class Withdrawal
24
25   #endif // WITHDRAWAL_H
```

Fig. 26.5 | Declaring references to objects associated with class `Withdrawal`.

introduces the name of the class as a new user-defined type and indicates the data members that determine how much memory is required to store the object. Declaring a *reference* (or pointer) to an object, however, requires only that the compiler knows that the object's class exists—it does not need to know the size of the object. Any reference (or pointer), regardless of the class of the object to which it refers, contains only the memory address of the actual object. The amount of memory required to store an address is a physical characteristic of the computer's hardware. The compiler thus knows the size of any reference (or pointer). As a result, including a class's full header file when declaring only a reference to an object of that class is unnecessary—we need to introduce the name of the class, but we do not need to provide the data layout of the object, because the compiler already knows the size of all references. C++ provides a statement called a **forward declaration** that signifies that a header file contains references or pointers to a class, but that the class definition lies outside the header file. We can replace the #includes in the Withdrawal class definition of Fig. 26.5 with forward declarations of classes Screen, Keypad, CashDispenser and BankDatabase (lines 6–9 in Fig. 26.6). Rather than #include the entire header file for each of these classes, we place only a forward declaration of each class in the header file for class Withdrawal. If class Withdrawal contained actual objects instead of references (i.e., if the ampersands in lines 19–22 were omitted), then we'd need to #include the full header files.

Using a forward declaration (where possible) instead of including a full header file helps avoid a preprocessor problem called a **circular include**. This problem oc-

curs when the header file for a class A #includes the header file for a class B and vice versa. Some preprocessors are not be able to resolve such #include directives, causing a compilation error. If class A, for example, uses only a reference to an object of class B, then the #include in class A's header file can be replaced by a forward declaration of class B to prevent the circular include.

```cpp
 1  // Fig. 26.6: Withdrawal.h
 2  // Definition of class Withdrawal that represents a withdrawal transaction
 3  #ifndef WITHDRAWAL_H
 4  #define WITHDRAWAL_H
 5
 6  class Screen; // forward declaration of class Screen
 7  class Keypad; // forward declaration of class Keypad
 8  class CashDispenser; // forward declaration of class CashDispenser
 9  class BankDatabase; // forward declaration of class BankDatabase
10
11  class Withdrawal
12  {
13  private:
14     // attributes
15     int accountNumber; // account to withdraw funds from
16     double amount; // amount to withdraw
17
18     // references to associated objects
19     Screen &screen; // reference to ATM's screen
20     Keypad &keypad; // reference to ATM's keypad
21     CashDispenser &cashDispenser; // reference to ATM's cash dispenser
22     BankDatabase &bankDatabase; // reference to the account info database
23  }; // end class Withdrawal
24
25  #endif // WITHDRAWAL_H
```

Fig. 26.6 | Using forward declarations in place of #include directives.

5. Use the operations located in the third compartment of Fig. 26.1 to write the function prototypes of the class's member functions. If we've not yet specified a return type for an operation, we declare the member function with return type void. Refer to the class diagrams of Figs. 6.21–6.24 to declare any necessary parameters. For example, adding the public operation execute in class Withdrawal, which has an empty parameter list, yields the prototype in line 15 of Fig. 26.7. [*Note:* We code the definitions of member functions in .cpp files when we implement the complete ATM system in Section 26.4.]

>
> *Several UML modeling tools can convert UML-based designs into C++ code, considerably speeding the implementation process. For more information on these "automatic" code generators, refer to our UML Resource Center at www.deitel.com/UML/.*

This concludes our discussion of the basics of generating class header files from UML diagrams. In Section 26.3, we demonstrate how to modify the header files to incorporate the object-oriented concept of inheritance.

```
 1   // Fig. 26.7: Withdrawal.h
 2   // Definition of class Withdrawal that represents a withdrawal transaction
 3   #ifndef WITHDRAWAL_H
 4   #define WITHDRAWAL_H
 5
 6   class Screen; // forward declaration of class Screen
 7   class Keypad; // forward declaration of class Keypad
 8   class CashDispenser; // forward declaration of class CashDispenser
 9   class BankDatabase; // forward declaration of class BankDatabase
10
11   class Withdrawal
12   {
13   public:
14      // operations
15      void execute(); // perform the transaction
16   private:
17      // attributes
18      int accountNumber; // account to withdraw funds from
19      double amount; // amount to withdraw
20
21      // references to associated objects
22      Screen &screen; // reference to ATM's screen
23      Keypad &keypad; // reference to ATM's keypad
24      CashDispenser &cashDispenser; // reference to ATM's cash dispenser
25      BankDatabase &bankDatabase; // reference to the account info database
26   }; // end class Withdrawal
27
28   #endif // WITHDRAWAL_H
```

Self-Review Exercises for Section 26.2

26.1   State whether the following statement is *true* or *false*, and if *false*, explain why: If an attribute of a class is marked with a minus sign (-) in a class diagram, the attribute is not directly accessible outside of the class.

26.2   In Fig. 26.2, the association between the ATM and the Screen indicates that:
   a) we can navigate from the Screen to the ATM
   b) we can navigate from the ATM to the Screen
   c) Both a and b; the association is bidirectional
   d) None of the above

26.3   Write C++ code to begin implementing the design for class Account.

26.3 Incorporating Inheritance into the ATM System

[*Note:* **This section can be studied after Chapter 12.**]

We now revisit our ATM system design to see how it might benefit from inheritance. To apply inheritance, we first look for *commonality* among classes in the system. We create an inheritance hierarchy to model similar (yet not identical) classes in a more efficient and elegant manner that enables us to process objects of these classes polymorphically. We then modify our class diagram to incorporate the new inheritance relationships. Finally, we demonstrate how our updated design is translated into C++ header files.

In Section 25.4, we encountered the problem of representing a financial transaction in the system. Rather than create one class to represent all transaction types, we decided to create three individual transaction classes—BalanceInquiry, Withdrawal and Deposit—to represent the transactions that the ATM system can perform. Figure 26.8 shows the attributes and operations of these classes, which have one attribute (accountNumber) and one operation (execute) in common. Each class requires attribute accountNumber to specify the account to which the transaction applies. Each class contains operation execute, which the ATM invokes to perform the transaction. Clearly, BalanceInquiry, Withdrawal and Deposit represent *types of* transactions. Figure 26.8 reveals commonality among the transaction classes, so using inheritance to factor out the common features seems appropriate for designing these classes. We place the common functionality in base class Transaction and derive classes BalanceInquiry, Withdrawal and Deposit from Transaction (Fig. 26.9).

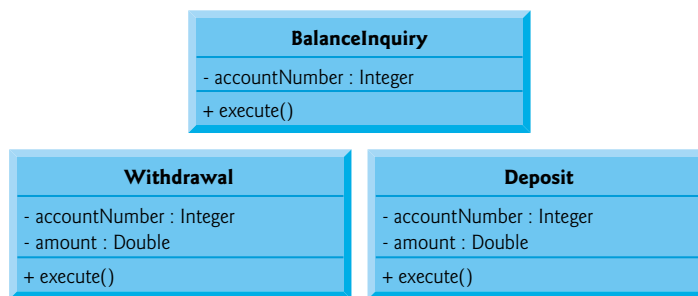

Fig. 26.8 | Attributes and operations of classes BalanceInquiry, Withdrawal and Deposit.

The UML specifies a relationship called a **generalization** to model inheritance. Figure 26.9 is the class diagram that models the inheritance relationship between base class Transaction and its three derived classes. The arrows with triangular hollow arrowheads indicate that classes BalanceInquiry, Withdrawal and Deposit are derived from class

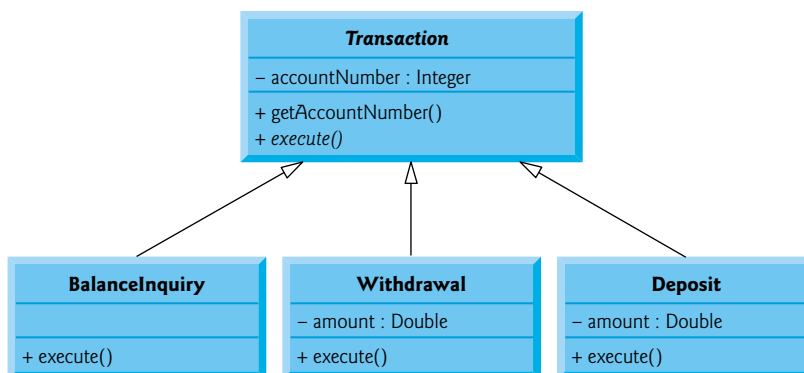

Fig. 26.9 | Class diagram modeling generalization relations\hip between base class Transaction and derived classes BalanceInquiry, Withdrawal and Deposit.

Transaction. Class Transaction is said to be a generalization of its derived classes. The derived classes are said to be **specializations** of class Transaction.

Classes BalanceInquiry, Withdrawal and Deposit share integer attribute account-Number, so we factor out this common attribute and place it in base class Transaction. We no longer list accountNumber in the second compartment of each derived class, because the three derived classes inherit this attribute from Transaction. Recall, however, that derived classes cannot access private attributes of a base class. We therefore include public member function getAccountNumber in class Transaction. Each derived class inherits this member function, enabling the derived class to access its accountNumber as needed to execute a transaction.

According to Fig. 26.8, classes BalanceInquiry, Withdrawal and Deposit also share operation execute, so base class Transaction should contain public member function execute. However, it does not make sense to implement execute in class Transaction, because the functionality that this member function provides depends on the specific type of the actual transaction. We therefore declare member function execute as a pure virtual function in base class Transaction. This makes Transaction an *abstract class* and forces any class derived from Transaction that must be a *concrete class* (i.e., BalanceInquiry, Withdrawal and Deposit) to implement pure virtual member function execute to make the derived class concrete. The UML requires that we place abstract class names (and pure virtual functions—**abstract operations** in the UML) in italics, so Transaction and its member function execute appear in italics in Fig. 26.9. Operation execute is not italicized in derived classes BalanceInquiry, Withdrawal and Deposit. Each derived class overrides base class Transaction's execute member function with an appropriate implementation. Figure 26.9 includes operation execute in the third compartment of classes BalanceInquiry, Withdrawal and Deposit, because each class has a different concrete implementation of the overridden member function.

Processing Transactions Polymorphically

A derived class can inherit interface and/or implementation from a base class. Compared to a hierarchy designed for implementation inheritance, one designed for interface inheritance tends to have its functionality lower in the hierarchy—a base class signifies one or more functions that should be defined by each class in the hierarchy, but the individual derived classes provide their own implementations of the function(s). The inheritance hierarchy designed for the ATM system takes advantage of this type of inheritance, which provides the ATM with an elegant way to execute all transactions "in the general." Each class derived from Transaction inherits some implementation details (e.g., data member accountNumber), but the primary benefit of incorporating inheritance into our system is that the derived classes share a common interface (e.g., pure virtual member function execute). The ATM can aim a Transaction pointer at any transaction, and when the ATM invokes execute through this pointer, the version of execute appropriate to that transaction (i.e., the version implemented in that derived class's .cpp file) runs automatically. For example, suppose a user chooses to perform a balance inquiry. The ATM aims a Transaction pointer at a new object of class BalanceInquiry; the compiler allows this because a BalanceInquiry *is a* Transaction. When the ATM uses this pointer to invoke execute, BalanceInquiry's version of execute is called.

This polymorphic approach also makes the system easily *extensible*. Should we wish to create a new transaction type (e.g., funds transfer or bill payment), we would just create

an additional `Transaction` derived class that overrides the `execute` member function with a version appropriate for the new transaction type. We would need to make only minimal changes to the system code to allow users to choose the new transaction type from the main menu and for the `ATM` to instantiate and execute objects of the new derived class. The `ATM` could execute transactions of the new type using the current code, because it executes all transactions identically.

As you learned earlier in the chapter, an abstract class like `Transaction` is one for which you never intend to instantiate objects. An abstract class simply declares common attributes and behaviors for its derived classes in an inheritance hierarchy. Class `Transaction` defines the concept of what it means to be a transaction that has an account number and executes. You may wonder why we bother to include pure `virtual` member function `execute` in class `Transaction` if `execute` lacks a concrete implementation. Conceptually, we include this member function because it's the defining behavior of all transactions—executing. Technically, we must include member function `execute` in base class `Transaction` so that the `ATM` (or any other class) can polymorphically invoke each derived class's overridden version of this function through a `Transaction` pointer or reference.

Additional Attribute of Classes *Withdrawal and Deposit*
Derived classes `BalanceInquiry`, `Withdrawal` and `Deposit` inherit attribute `accountNumber` from base class `Transaction`, but classes `Withdrawal` and `Deposit` contain the additional attribute `amount` that distinguishes them from class `BalanceInquiry`. Classes `Withdrawal` and `Deposit` require this additional attribute to store the amount of money that the user wishes to withdraw or deposit. Class `BalanceInquiry` has no need for such an attribute and requires only an account number to execute. Even though two of the three `Transaction` derived classes share this attribute, we do not place it in base class `Transaction`—we place only features common to *all* the derived classes in the base class, so derived classes do not inherit unnecessary attributes (and operations).

Class Diagram with *Transaction* Hierarchy Incorporated
Figure 26.10 presents an updated class diagram of our model that incorporates inheritance and introduces class `Transaction`. We model an association between class `ATM` and class `Transaction` to show that the `ATM`, at any given moment, either is executing a transaction or is not (i.e., zero or one objects of type `Transaction` exist in the system at a time). Because a `Withdrawal` is a type of `Transaction`, we no longer draw an association line directly between class `ATM` and class `Withdrawal`—derived class `Withdrawal` inherits base class `Transaction`'s association with class `ATM`. Derived classes `BalanceInquiry` and `Deposit` also inherit this association, which replaces the previously omitted associations between classes `BalanceInquiry` and `Deposit` and class `ATM`. Note again the use of triangular hollow arrowheads to indicate the specializations of class `Transaction`, as indicated in Fig. 26.9.

We also add an association between class `Transaction` and the `BankDatabase` (Fig. 26.10). All `Transactions` require a reference to the `BankDatabase` so they can access and modify account information. Each `Transaction` derived class inherits this reference, so we no longer model the association between class `Withdrawal` and the `BankDatabase`. The association between class `Transaction` and the `BankDatabase` replaces the previously omitted associations between classes `BalanceInquiry` and `Deposit` and the `BankDatabase`.

We include an association between class `Transaction` and the `Screen` because all `Transactions` display output to the user via the `Screen`. Each derived class inherits this
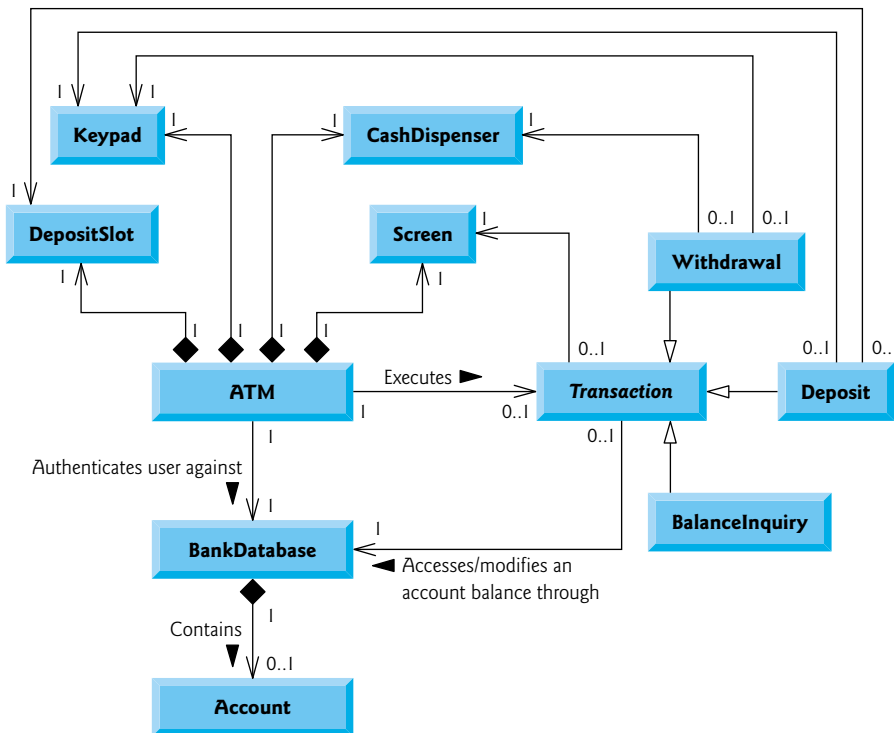

Fig. 26.10 | Class diagram of the ATM system (incorporating inheritance). Note that abstract class name `Transaction` appears in italics.

association. Therefore, we no longer include the association previously modeled between `Withdrawal` and the `Screen`. Class `Withdrawal` still participates in associations with the `CashDispenser` and the `Keypad`. We do not move these associations to base class `Transaction`, because the association with the `Keypad` applies only to classes `Withdrawal` and `Deposit`, and the association with the `CashDispenser` applies only to class `Withdrawal`.

Our class diagram incorporating inheritance (Fig. 26.10) also models `Deposit` and `BalanceInquiry`. We show associations between `Deposit` and both the `DepositSlot` and the `Keypad`. `BalanceInquiry` takes part in no associations other than those inherited from class `Transaction`—a `BalanceInquiry` interacts only with the `BankDatabase` and the `Screen`.

Figure 26.1 showed attributes and operations with visibility markers. Now we present a modified class diagram in Fig. 26.11 that includes abstract base class `Transaction`. This abbreviated diagram does not show inheritance relationships (these appear in Fig. 26.10), but instead shows the attributes and operations after we've employed inheritance in our system. Abstract class name `Transaction` and abstract operation name `execute` in class `Transaction` appear in *italics*. To save space, we do not include those attributes shown by associations in Fig. 26.10—we do, however, include them in the C++ implementation. We also omit all operation parameters, as we did in Fig. 26.1—incorporating inheritance does not affect the parameters already modeled in Figs. 25.18–25.21.

Software Engineering Observation 26.2

A complete class diagram shows all the associations among classes and all the attributes and operations for each class. When the number of class attributes, operations and associations is substantial (as in Fig. 26.10 and Fig. 26.11), a good practice that promotes readability is to divide this information between two class diagrams—one focusing on associations and the other on attributes and operations. However, when examining classes modeled in this fashion, it's crucial to consider both class diagrams to get a complete view of the classes. For example, one must refer to Fig. 26.10 to observe the inheritance relationship between Transaction *and its derived classes that is omitted from Fig. 26.11.*

Implementing the ATM System Design Incorporating Inheritance
We now modify our implementation to incorporate inheritance, using class Withdrawal as an example.

1. If a class A is a generalization of class B, then class B is derived from (and is a specialization of) class A. For example, abstract base class Transaction is a generalization of class Withdrawal. Thus, class Withdrawal is derived from (and is a specialization of) class Transaction. Figure 26.12 contains a portion of class Withdrawal's header file, in which the class definition indicates the inheritance relationship between Withdrawal and Transaction (line 9).

```
 1   // Fig. 26.12: Withdrawal.h
 2   // Definition of class Withdrawal that represents a withdrawal transaction
 3   #ifndef WITHDRAWAL_H
 4   #define WITHDRAWAL_H
 5
 6   #include "Transaction.h" // Transaction class definition
 7
 8   // class Withdrawal derives from base class Transaction
 9   class Withdrawal : public Transaction
10   {
11   }; // end class Withdrawal
12
13   #endif // WITHDRAWAL_H
```

Fig. 26.12 | Withdrawal class definition that derives from Transaction.

2. If class A is an abstract class and class B is derived from class A, then class B must implement the pure virtual functions of class A if class B is to be a concrete class. For example, class Transaction contains pure virtual function execute, so class Withdrawal must implement this member function if we want to instantiate a Withdrawal object. Figure 26.13 contains the C++ header file for class Withdrawal from Fig. 26.10 and Fig. 26.11. Class Withdrawal inherits data member accountNumber from base class Transaction, so Withdrawal does not declare this data member. Class Withdrawal also inherits references to the Screen and the BankDatabase from its base class Transaction, so we do not include these references in our code. Figure 26.11 specifies attribute amount and operation execute for class Withdrawal. Line 19 of Fig. 26.13 declares a data member for attribute amount. Line 16 contains the function prototype for operation execute. Recall that, to be a concrete class, derived class Withdrawal must provide a concrete implementation of the pure virtual function execute in base class Transaction. The prototype in line 16 signals your intent to override the base class pure virtual function. You must provide this prototype if you'll provide an implementation in the .cpp file. We present this implementation in Section 26.4. The keypad and cashDispenser references (lines 20–21) are data members derived from Withdrawal's associations in Fig. 26.10. In the implementation of this class in Section 26.4, a constructor initializes these references to actual objects. Once again, to be able to compile the declarations of the references in lines 20–21, we include the forward declarations in lines 8–9.

ATM Case Study Wrap-Up

This concludes our object-oriented design of the ATM system. A complete C++ implementation of the ATM system in 850 lines of code appears in Section 26.4. This working

```
1   // Fig. 26.13: Withdrawal.h
2   // Definition of class Withdrawal that represents a withdrawal transaction
3   #ifndef WITHDRAWAL_H
4   #define WITHDRAWAL_H
5
6   #include "Transaction.h" // Transaction class definition
7
8   class Keypad; // forward declaration of class Keypad
9   class CashDispenser; // forward declaration of class CashDispenser

implementation uses key programming notions, including classes, objects, encapsulation, visibility, composition, inheritance and polymorphism. The code is abundantly commented and conforms to the coding practices you've learned. Mastering this code is a wonderful capstone experience.

Self-Review Exercises for Section 26.3

26.4   The UML uses an arrow with a _____ to indicate a generalization relationship.
a) solid filled arrowhead
b) triangular hollow arrowhead
c) diamond-shaped hollow arrowhead
d) stick arrowhead

26.5   State whether the following statement is *true* or *false*, and if *false*, explain why: The UML requires that we underline abstract class names and operation names.

26.6   Write a C++ header file to begin implementing the design for class `Transaction` specified in Fig. 26.10 and Fig. 26.11. Be sure to include `private` references based on class `Transaction`'s associations. Also be sure to include `public` *get* functions for any of the `private` data members that the derived classes must access to perform their tasks.

26.4 ATM Case Study Implementation

This section contains the complete working implementation of the ATM system that we designed in Chapter 25 and this chapter. We consider the classes in the order in which we identified them in Section 25.4:

- ATM
- Screen
- Keypad
- CashDispenser
- DepositSlot
- Account
- BankDatabase
- Transaction
- BalanceInquiry
- Withdrawal
- Deposit

We apply the guidelines discussed in Sections 26.2 and 26.3 to code these classes based on how we modeled them in the UML class diagrams of Figs. 26.10 and 26.11. To develop the definitions of classes' member functions, we refer to the activity diagrams presented in Section 25.6 and the communication and sequence diagrams presented in Section 25.8. Note that our ATM design does not specify all the program logic and may not specify all the attributes and operations required to complete the ATM implementation. This is a normal part of the object-oriented design process. As we implement the system, we complete the program logic and add attributes and behaviors as necessary to construct the ATM system specified by the requirements specification in Section 25.3.

We conclude the discussion by presenting a C++ program (ATMCaseStudy.cpp) that starts the ATM and puts the other classes in the system in use. Recall that we're developing a first version of the ATM system that runs on a personal computer and uses the computer's keyboard and monitor to approximate the ATM's keypad and screen. We also only simulate the actions of the ATM's cash dispenser and deposit slot. We attempt to implement the system, however, so that real hardware versions of these devices could be integrated without significant changes in the code.

26.4.1 Class ATM

Class ATM (Figs. 26.14–26.15) represents the ATM as a whole. Figure 26.14 contains the ATM class definition, enclosed in #ifndef, #define and #endif preprocessor directives to ensure that this definition gets included only once in a program. We discuss lines 6–11 shortly. Lines 16–17 contain the function prototypes for the class's public member functions. The class diagram of Fig. 26.11 does not list any operations for class ATM, but we now declare a public member function run (line 17) in class ATM that allows an external client of the class (i.e., ATMCaseStudy.cpp) to tell the ATM to run. We also include a function prototype for a default constructor (line 16), which we discuss shortly.

```
1   // ATM.h
2   // ATM class definition. Represents an automated teller machine.
3   #ifndef ATM_H
```

Fig. 26.14 | Definition of class ATM, which represents the ATM. (Part 1 of 2.)

```
4    #define ATM_H
5
6    #include "Screen.h" // Screen class definition
7    #include "Keypad.h" // Keypad class definition
8    #include "CashDispenser.h" // CashDispenser class definition
9    #include "DepositSlot.h" // DepositSlot class definition
10   #include "BankDatabase.h" // BankDatabase class definition
11   class Transaction; // forward declaration of class Transaction
12
13   class ATM
14   {
15   public:
16      ATM(); // constructor initializes data members
17      void run(); // start the ATM
18   private:
19      bool userAuthenticated; // whether user is authenticated
20      int currentAccountNumber; // current user's account number
21      Screen screen; // ATM's screen
22      Keypad keypad; // ATM's keypad
23      CashDispenser cashDispenser; // ATM's cash dispenser
24      DepositSlot depositSlot; // ATM's deposit slot
25      BankDatabase bankDatabase; // account information database
26
27      // private utility functions
28      void authenticateUser(); // attempts to authenticate user
29      void performTransactions(); // performs transactions
30      int displayMainMenu() const; // displays main menu
31
32      // return object of specified Transaction derived class
33      Transaction *createTransaction( int );
34   }; // end class ATM
35
36   #endif // ATM_H
```

Fig. 26.14 | Definition of class ATM, which represents the ATM. (Part 2 of 2.)

Lines 19–25 of Fig. 26.14 implement the class's attributes as private data members. We determine all but one of these attributes from the class diagrams of Figs. 26.10– 26.11. We implement the UML Boolean attribute userAuthenticated in Fig. 26.11 as a bool data member in C++ (line 19). Line 20 declares a data member not found in our UML design—an int data member currentAccountNumber that keeps track of the account number of the current authenticated user. We'll soon see how the class uses this data member.

Lines 21–24 create objects to represent the parts of the ATM. Recall from the class diagram of Fig. 26.10 that class ATM has composition relationships with classes Screen, Keypad, CashDispenser and DepositSlot, so class ATM is responsible for their creation. Line 25 creates a BankDatabase, with which the ATM interacts to access and manipulate bank account information. [*Note:* If this were a real ATM system, the ATM class would receive a reference to an existing database object created by the bank. However, in this implementation we are only simulating the bank's database, so class ATM creates the Bank-Database object with which it interacts.] Lines 6–10 #include the class definitions of

Screen, Keypad, CashDispenser, DepositSlot and BankDatabase so that the ATM can store objects of these classes.

Lines 28–30 and 33 contain function prototypes for private utility functions that the class uses to perform its tasks. We'll see how these functions serve the class shortly. Member function createTransaction (line 33) returns a Transaction pointer. To include the class name Transaction in this file, we must at least include a forward declaration of class Transaction (line 11). Recall that a forward declaration tells the compiler that a class exists, but that the class is defined elsewhere. A forward declaration is sufficient here, as we are using a Transaction pointer as a return type—if we were creating or returning an actual Transaction object, we would need to #include the full Transaction header file.

ATM Class Member-Function Definitions

Figure 26.15 contains the member-function definitions for class ATM. Lines 3–7 #include the header files required by the implementation file ATM.cpp. Including the ATM header file allows the compiler to ensure that the class's member functions are defined correctly. This also allows the member functions to use the class's data members.

```cpp
1   // ATM.cpp
2   // Member-function definitions for class ATM.
3   #include "ATM.h" // ATM class definition
4   #include "Transaction.h" // Transaction class definition
5   #include "BalanceInquiry.h" // BalanceInquiry class definition
6   #include "Withdrawal.h" // Withdrawal class definition
7   #include "Deposit.h" // Deposit class definition
8
9   // enumeration constants represent main menu options
10  enum MenuOption { BALANCE_INQUIRY = 1, WITHDRAWAL, DEPOSIT, EXIT };
11
12  // ATM default constructor initializes data members
13  ATM::ATM()
14     : userAuthenticated ( false ), // user is not authenticated to start
15       currentAccountNumber( 0 ) // no current account number to start
16  {
17     // empty body
18  } // end ATM default constructor
19
20  // start ATM
21  void ATM::run()
22  {
23     // welcome and authenticate user; perform transactions
24     while ( true )
25     {
26        // loop while user is not yet authenticated
27        while ( !userAuthenticated )
28        {
29           screen.displayMessageLine( "\nWelcome!" );
30           authenticateUser(); // authenticate user
31        } // end while
32
```

Fig. 26.15 | ATM class member-function definitions. (Part 1 of 4.)

```
33            performTransactions(); // user is now authenticated
34            userAuthenticated = false; // reset before next ATM session
35            currentAccountNumber = 0; // reset before next ATM session
36            screen.displayMessageLine( "\nThank you! Goodbye!" );
37         } // end while
38     } // end function run
39
40     // attempt to authenticate user against database
41     void ATM::authenticateUser()
42     {
43         screen.displayMessage( "\nPlease enter your account number: " );
44         int accountNumber = keypad.getInput(); // input account number
45         screen.displayMessage( "\nEnter your PIN: " ); // prompt for PIN
46         int pin = keypad.getInput(); // input PIN
47
48         // set userAuthenticated to bool value returned by database
49         userAuthenticated =
50             bankDatabase.authenticateUser( accountNumber, pin );
51
52         // check whether authentication succeeded
53         if ( userAuthenticated )
54         {
55             currentAccountNumber = accountNumber; // save user's account #
56         } // end if
57         else
58             screen.displayMessageLine(
59                 "Invalid account number or PIN. Please try again." );
60     } // end function authenticateUser
61
62     // display the main menu and perform transactions
63     void ATM::performTransactions()
64     {
65         // local pointer to store transaction currently being processed
66         Transaction *currentTransactionPtr;
67
68         bool userExited = false; // user has not chosen to exit
69
70         // loop while user has not chosen option to exit system
71         while ( !userExited )
72         {
73             // show main menu and get user selection
74             int mainMenuSelection = displayMainMenu();
75
76             // decide how to proceed based on user's menu selection
77             switch ( mainMenuSelection )
78             {
79                 // user chose to perform one of three transaction types
80                 case BALANCE_INQUIRY:
81                 case WITHDRAWAL:
82                 case DEPOSIT:
83                     // initialize as new object of chosen type
84                     currentTransactionPtr =
85                         createTransaction( mainMenuSelection );
```

Fig. 26.15 | ATM class member-function definitions. (Part 2 of 4.)

```
86
87                 currentTransactionPtr->execute(); // execute transaction
88
89                 // free the space for the dynamically allocated Transaction
90                 delete currentTransactionPtr;
91
92                 break;
93             case EXIT: // user chose to terminate session
94                 screen.displayMessageLine( "\nExiting the system..." );
95                 userExited = true; // this ATM session should end
96                 break;
97             default: // user did not enter an integer from 1-4
98                 screen.displayMessageLine(
99                     "\nYou did not enter a valid selection. Try again." );
100                break;
101        } // end switch
102     } // end while
103 } // end function performTransactions
104
105 // display the main menu and return an input selection
106 int ATM::displayMainMenu() const
107 {
108     screen.displayMessageLine( "\nMain menu:" );
109     screen.displayMessageLine( "1 - View my balance" );
110     screen.displayMessageLine( "2 - Withdraw cash" );
111     screen.displayMessageLine( "3 - Deposit funds" );
112     screen.displayMessageLine( "4 - Exit\n" );
113     screen.displayMessage( "Enter a choice: " );
114     return keypad.getInput(); // return user's selection
115 } // end function displayMainMenu
116
117 // return object of specified Transaction derived class
118 Transaction *ATM::createTransaction( int type )
119 {
120     Transaction *tempPtr; // temporary Transaction pointer
121
122     // determine which type of Transaction to create
123     switch ( type )
124     {
125         case BALANCE_INQUIRY: // create new BalanceInquiry transaction
126             tempPtr = new BalanceInquiry(
127                 currentAccountNumber, screen, bankDatabase );
128             break;
129         case WITHDRAWAL: // create new Withdrawal transaction
130             tempPtr = new Withdrawal( currentAccountNumber, screen,
131                 bankDatabase, keypad, cashDispenser );
132             break;
133         case DEPOSIT: // create new Deposit transaction
134             tempPtr = new Deposit( currentAccountNumber, screen,
135                 bankDatabase, keypad, depositSlot );
136             break;
137     } // end switch
138
```

Fig. 26.15 | ATM class member-function definitions. (Part 3 of 4.)

```
139     return tempPtr; // return the newly created object
140 } // end function createTransaction
```

Fig. 26.15 | ATM class member-function definitions. (Part 4 of 4.)

Line 10 declares an enum named MenuOption that contains constants corresponding to the four options in the ATM's main menu (i.e., balance inquiry, withdrawal, deposit and exit). Note that setting BALANCE_INQUIRY to 1 causes the subsequent enumeration constants to be assigned the values 2, 3 and 4, as enumeration constant values increment by 1.

Lines 13–18 define class ATM's constructor, which initializes the class's data members. When an ATM object is first created, no user is authenticated, so line 14 uses a member initializer to set userAuthenticated to false. Likewise, line 15 initializes currentAccountNumber to 0 because there is no current user yet.

ATM Member Function run

ATM member function run (lines 21–38) uses an infinite loop (lines 24–37) to repeatedly welcome a user, attempt to authenticate the user and, if authentication succeeds, allow the user to perform transactions. After an authenticated user performs the desired transactions and chooses to exit, the ATM resets itself, displays a goodbye message to the user and restarts the process. We use an infinite loop here to simulate the fact that an ATM appears to run continuously until the bank turns it off (an action beyond the user's control). An ATM user has the option to exit the system, but does not have the ability to turn off the ATM completely.

Authenticating a User

Inside member function run's infinite loop, lines 27–31 cause the ATM to repeatedly welcome and attempt to authenticate the user as long as the user has not been authenticated (i.e., !userAuthenticated is true). Line 29 invokes member function displayMessageLine of the ATM's screen to display a welcome message. Like Screen member function displayMessage designed in the case study, member function displayMessageLine (declared in line 13 of Fig. 26.16 and defined in lines 20–23 of Fig. 26.17) displays a message to the user, but this member function also outputs a newline after displaying the message. We've added this member function during implementation to give class Screen's clients more control over the placement of displayed messages. Line 30 of Fig. 26.15 invokes class ATM's private utility function authenticateUser (lines 41–60) to attempt to authenticate the user.

We refer to the requirements specification to determine the steps necessary to authenticate the user before allowing transactions to occur. Line 43 of member function authenticateUser invokes member function displayMessage of the ATM's screen to prompt the user to enter an account number. Line 44 invokes member function getInput of the ATM's keypad to obtain the user's input, then stores the integer value entered by the user in a local variable accountNumber. Member function authenticateUser next prompts the user to enter a PIN (line 45), and stores the PIN input by the user in a local variable pin (line 46). Next, lines 49–50 attempt to authenticate the user by passing the accountNumber and pin entered by the user to the bankDatabase's authenticateUser member function. Class ATM sets its userAuthenticated data member to the bool value returned by this function—userAuthenticated becomes true if authentication succeeds (i.e., accountNumber and pin match those of an existing Account in bankDatabase) and remains false otherwise.

If `userAuthenticated` is `true`, line 55 saves the account number entered by the user (i.e., `accountNumber`) in the `ATM` data member `currentAccountNumber`. The other member functions of class `ATM` use this variable whenever an ATM session requires access to the user's account number. If `userAuthenticated` is `false`, lines 58–59 use the `screen`'s `display-MessageLine` member function to indicate that an invalid account number and/or PIN was entered and the user must try again. Note that we set `currentAccountNumber` only after authenticating the user's account number and the associated PIN—if the database could not authenticate the user, `currentAccountNumber` remains 0.

After member function `run` attempts to authenticate the user (line 30), if `user-Authenticated` is still `false`, the `while` loop in lines 27–31 executes again. If `user-Authenticated` is now `true`, the loop terminates and control continues with line 33, which calls class `ATM`'s utility function `performTransactions`.

Performing Transactions

Member function `performTransactions` (lines 63–103) carries out an ATM session for an authenticated user. Line 66 declares a local `Transaction` pointer, which we aim at a `BalanceInquiry`, `Withdrawal` or `Deposit` object representing the ATM transaction currently being processed. We use a `Transaction` pointer here to allow us to take advantage of polymorphism. Also, we use the role name included in the class diagram of Fig. 25.7—`currentTransaction`—in naming this pointer. As per our pointer-naming convention, we append "Ptr" to the role name to form the variable name `currentTransactionPtr`. Line 68 declares another local variable—a `bool` called `userExited` that keeps track of whether the user has chosen to exit. This variable controls a `while` loop (lines 71–102) that allows the user to execute an unlimited number of transactions before choosing to exit. Within this loop, line 74 displays the main menu and obtains the user's menu selection by calling an `ATM` utility function `displayMainMenu` (defined in lines 106–115). This member function displays the main menu by invoking member functions of the `ATM`'s `screen` and returns a menu selection obtained from the user through the `ATM`'s `keypad`. Note that this member function is `const` because it does not modify the contents of the object. Line 74 stores the user's selection returned by `displayMainMenu` in local variable `mainMenuSelection`.

After obtaining a main menu selection, member function `performTransactions` uses a `switch` statement (lines 77–101) to respond to the selection appropriately. If `main-MenuSelection` is equal to any of the three enumeration constants representing transaction types (i.e., if the user chose to perform a transaction), lines 84–85 call utility function `createTransaction` (defined in lines 118–140) to return a pointer to a newly instantiated object of the type that corresponds to the selected transaction. Pointer `currentTransactionPtr` is assigned the pointer returned by `createTransaction`. Line 87 then uses `currentTransactionPtr` to invoke the new object's `execute` member function to execute the transaction. We'll discuss `Transaction` member function `execute` and the three `Transaction` derived classes shortly. Finally, when the `Transaction` derived class object is no longer needed, line 90 releases the memory dynamically allocated for it.

We aim the `Transaction` pointer `currentTransactionPtr` at an object of one of the three `Transaction` derived classes so that we can execute transactions *polymorphically*. For example, if the user chooses to perform a balance inquiry, `mainMenuSelection` equals `BALANCE_INQUIRY`, leading `createTransaction` to return a pointer to a `BalanceInquiry` object. Thus, `currentTransactionPtr` points to a `BalanceInquiry`, and invoking `current-TransactionPtr->execute()` results in `BalanceInquiry`'s version of `execute` being called.

Creating a Transaction

Member function `createTransaction` (lines 118–140) uses a `switch` statement (lines 123–137) to instantiate a new `Transaction` derived class object of the type indicated by the parameter `type`. Recall that member function `performTransactions` passes `main-MenuSelection` to this member function only when `mainMenuSelection` contains a value corresponding to one of the three transaction types. Therefore `type` equals either `BALANCE_INQUIRY`, `WITHDRAWAL` or `DEPOSIT`. Each `case` in the `switch` statement aims the temporary pointer `tempPtr` at a newly created object of the appropriate `Transaction` derived class. Each constructor has a unique parameter list, based on the specific data required to initialize the derived class object. A `BalanceInquiry` requires only the account number of the current user and references to the ATM's `screen` and the `bankDatabase`. In addition to these parameters, a `Withdrawal` requires references to the ATM's `keypad` and `cashDispenser`, and a `Deposit` requires references to the ATM's `keypad` and `depositSlot`. As you'll soon see, the `BalanceInquiry`, `Withdrawal` and `Deposit` constructors each specify reference parameters to receive the objects representing the required parts of the ATM. Thus, when member function `createTransaction` passes objects in the ATM (e.g., `screen` and `keypad`) to the initializer for each newly created `Transaction` derived class object, the new object actually receives *references* to the ATM's composite objects. We discuss the transaction classes in more detail in Sections 26.4.8–26.4.11.

Exiting the Main Menu and Processing Invalid Selections

After executing a transaction (line 87 in `performTransactions`), `userExited` remains `false` and the `while` loop in lines 71–102 repeats, returning the user to the main menu. However, if a user does not perform a transaction and instead selects the main menu option to exit, line 95 sets `userExited` to `true`, causing the condition of the `while` loop (`!userExited`) to become `false`. This `while` is the final statement of member function `performTransactions`, so control returns to the calling function `run`. If the user enters an invalid main menu selection (i.e., not an integer from 1–4), lines 98–99 display an appropriate error message, `userExited` remains `false` and the user returns to the main menu to try again.

Awaiting the Next ATM User

When `performTransactions` returns control to member function `run`, the user has chosen to exit the system, so lines 34–35 reset the ATM's data members `userAuthenticated` and `currentAccountNumber` to prepare for the next ATM user. Line 36 displays a goodbye message before the ATM starts over and welcomes the next user.

26.4.2 Class Screen

Class `Screen` (Figs. 26.16–26.17) represents the screen of the ATM and encapsulates all aspects of displaying output to the user. Class `Screen` approximates a real ATM's screen with a computer monitor and outputs text messages using `cout` and the stream insertion operator (`<<`). In this case study, we designed class `Screen` to have one operation—`displayMessage`. For greater flexibility in displaying messages to the `Screen`, we now declare three `Screen` member functions—`displayMessage`, `displayMessageLine` and `displayDollarAmount`. The prototypes for these member functions appear in lines 12–14 of Fig. 26.16.

```
 1   // Screen.h
 2   // Screen class definition. Represents the screen of the ATM.
 3   #ifndef SCREEN_H
 4   #define SCREEN_H
 5
 6   #include <string>
 7   using namespace std;
 8
 9   class Screen
10   {
11   public:
12      void displayMessage( string ) const; // output a message
13      void displayMessageLine( string ) const; // output message with newline
14      void displayDollarAmount( double ) const; // output a dollar amount
15   }; // end class Screen
16
17   #endif // SCREEN_H
```

Fig. 26.16 | Screen class definition.

```
 1   // Screen.cpp
 2   // Member-function definitions for class Screen.
 3   #include <iostream>
 4   #include <iomanip>
 5   #include "Screen.h" // Screen class definition
 6   using namespace std;
 7
 8   // output a message without a newline
 9   void Screen::displayMessage( string message ) const
10   {
11      cout << message;
12   } // end function displayMessage
13
14   // output a message with a newline
15   void Screen::displayMessageLine( string message ) const
16   {
17      cout << message << endl;
18   } // end function displayMessageLine
19
20   // output a dollar amount
21   void Screen::displayDollarAmount( double amount ) const
22   {
23      cout << fixed << setprecision( 2 ) << "$" << amount;
24   } // end function displayDollarAmount
```

Fig. 26.17 | Screen class member-function definitions.

Screen Class Member-Function Definitions

Figure 26.17 contains the member-function definitions for class Screen. Line 5 #includes the Screen class definition. Member function displayMessage (lines 9–12) takes a string as an argument and prints it to the console using cout and the stream insertion operator (<<). The cursor stays on the same line, making this member function appropri-

ate for displaying prompts to the user. Member function `displayMessageLine` (lines 15–18) also prints a `string`, but outputs a newline to move the cursor to the next line. Finally, member function `displayDollarAmount` (lines 21–24) outputs a properly formatted dollar amount (e.g., $123.45). Line 23 uses stream manipulators `fixed` and `setprecision` to output a value formatted with two decimal places.

26.4.3 Class Keypad

Class `Keypad` (Figs. 26.18–26.19) represents the keypad of the ATM and is responsible for receiving all user input. Recall that we are simulating this hardware, so we use the computer's keyboard to approximate the keypad. A computer keyboard contains many keys not found on the ATM's keypad. However, we assume that the user presses only the keys on the computer keyboard that also appear on the keypad—the keys numbered 0–9 and the *Enter* key. Line 9 of Fig. 26.18 contains the function prototype for class `Keypad`'s one member function `getInput`. This member function is declared `const` because it does not change the object.

```
1   // Keypad.h
2   // Keypad class definition. Represents the keypad of the ATM.
3   #ifndef KEYPAD_H
4   #define KEYPAD_H
5
6   class Keypad
7   {
8   public:
9      int getInput() const; // return an integer value entered by user
10  }; // end class Keypad
11
12  #endif // KEYPAD_H
```

Fig. 26.18 | Keypad class definition.

Keypad Class Member-Function Definition
In the `Keypad` implementation file (Fig. 26.19), member function `getInput` (defined in lines 9–14) uses the standard input stream `cin` and the stream extraction operator (>>) to obtain input from the user. Line 11 declares a local variable to store the user's input. Line 12 reads input into local variable `input`, then line 13 returns this value. Recall that `getInput` obtains all the input used by the ATM. `Keypad`'s `getInput` member function simply returns the integer input by the user. If a client of class `Keypad` requires input that satisfies some particular criteria (i.e., a number corresponding to a valid menu option), the client must perform the appropriate error checking. [*Note:* Using the standard input stream `cin` and the stream extraction operator (>>) allows noninteger input to be read from the user. Because the real ATM's keypad permits only integer input, however, we assume that the user enters an integer and do not attempt to fix problems caused by noninteger input.]

```
1   // Keypad.cpp
2   // Member-function definition for class Keypad (the ATM's keypad).
3   #include <iostream>
```

Fig. 26.19 | Keypad class member-function definition. (Part 1 of 2.)

```
 4   using namespace std;
 5
 6   #include "Keypad.h" // Keypad class definition
 7
 8   // return an integer value entered by user
 9   int Keypad::getInput() const
10   {
11      int input; // variable to store the input
12      cin >> input; // we assume that user enters an integer
13      return input; // return the value entered by user
14   } // end function getInput
```

Fig. 26.19 | Keypad class member-function definition. (Part 2 of 2.)

26.4.4 Class CashDispenser

Class CashDispenser (Figs. 26.20–26.21) represents the cash dispenser. Figure 26.20 contains the function prototype for a default constructor (line 9). Class CashDispenser declares two additional public member functions—dispenseCash (line 12) and isSufficientCashAvailable (line 15). The class trusts that a client (i.e., Withdrawal) calls dispenseCash only after establishing that sufficient cash is available by calling isSufficientCashAvailable. Thus, dispenseCash simply simulates dispensing the requested amount without checking whether sufficient cash is available. Line 17 declares private constant INITIAL_COUNT, which indicates the initial count of bills in the cash dispenser when the ATM starts (i.e., 500). Line 18 implements attribute count (modeled in Fig. 26.11), which keeps track of the number of bills remaining in the CashDispenser at any time.

```
 1   // CashDispenser.h
 2   // CashDispenser class definition. Represents the ATM's cash dispenser.
 3   #ifndef CASH_DISPENSER_H
 4   #define CASH_DISPENSER_H
 5
 6   class CashDispenser
 7   {
 8   public:
 9      CashDispenser(); // constructor initializes bill count to 500
10
11      // simulates dispensing of specified amount of cash
12      void dispenseCash( int );
13
14      // indicates whether cash dispenser can dispense desired amount
15      bool isSufficientCashAvailable( int ) const;
16   private:
17      static const int INITIAL_COUNT = 500;
18      int count; // number of $20 bills remaining
19   }; // end class CashDispenser
20
21   #endif // CASH_DISPENSER_H
```

Fig. 26.20 | CashDispenser class definition.

CashDispenser Class Member-Function Definitions

Figure 26.21 contains the definitions of class `CashDispenser`'s member functions. The constructor (lines 6–9) sets `count` to the initial count (i.e., 500). Member function `dispenseCash` (lines 13–17) simulates cash dispensing. If our system were hooked up to a real hardware cash dispenser, this member function would interact with the hardware device to physically dispense cash. Our simulated version of the member function simply decreases the `count` of bills remaining by the number required to dispense the specified `amount` (line 16). Line 15 calculates the number of $20 bills required to dispense the specified `amount`. The ATM allows the user to choose only withdrawal amounts that are multiples of $20, so we divide `amount` by 20 to obtain the number of `billsRequired`. Also, it's the responsibility of the class's client (i.e., `Withdrawal`) to inform the user that cash has been dispensed—`CashDispenser` cannot interact directly with `Screen`.

```cpp
1   // CashDispenser.cpp
2   // Member-function definitions for class CashDispenser.
3   #include "CashDispenser.h" // CashDispenser class definition
4
5   // CashDispenser default constructor initializes count to default
6   CashDispenser::CashDispenser()
7   {
8      count = INITIAL_COUNT; // set count attribute to default
9   } // end CashDispenser default constructor
10
11  // simulates dispensing of specified amount of cash; assumes enough cash
12  // is available (previous call to isSufficientCashAvailable returned true)
13  void CashDispenser::dispenseCash( int amount )
14  {
15     int billsRequired = amount / 20; // number of $20 bills required
16     count -= billsRequired; // update the count of bills
17  } // end function dispenseCash
18
19  // indicates whether cash dispenser can dispense desired amount
20  bool CashDispenser::isSufficientCashAvailable( int amount ) const
21  {
22     int billsRequired = amount / 20; // number of $20 bills required
23
24     if ( count >= billsRequired )
25        return true; // enough bills are available
26     else
27        return false; // not enough bills are available
28  } // end function isSufficientCashAvailable
```

Fig. 26.21 | `CashDispenser` class member-function definitions.

Member function `isSufficientCashAvailable` (lines 20–28) has a parameter `amount` that specifies the amount of cash in question. Lines 24–27 return `true` if the `CashDispenser`'s `count` is greater than or equal to `billsRequired` (i.e., enough bills are available) and `false` otherwise (i.e., not enough bills). For example, if a user wishes to withdraw $80 (i.e., `billsRequired` is 4), but only three bills remain (i.e., `count` is 3), the member function returns `false`.

26.4.5 Class DepositSlot

Class DepositSlot (Figs. 26.22–26.23) represents the deposit slot of the ATM. Like the version of class CashDispenser presented here, this version of class DepositSlot merely simulates the functionality of a real hardware deposit slot. DepositSlot has no data members and only one member function—isEnvelopeReceived (declared in line 9 of Fig. 26.22 and defined in lines 7–10 of Fig. 26.23)—that indicates whether a deposit envelope was received.

```cpp
1   // DepositSlot.h
2   // DepositSlot class definition. Represents the ATM's deposit slot.
3   #ifndef DEPOSIT_SLOT_H
4   #define DEPOSIT_SLOT_H
5
6   class DepositSlot
7   {
8   public:
9      bool isEnvelopeReceived() const; // tells whether envelope was received
10  }; // end class DepositSlot
11
12  #endif // DEPOSIT_SLOT_H
```

Fig. 26.22 | DepositSlot class definition.

```cpp
1   // DepositSlot.cpp
2   // Member-function definition for class DepositSlot.
3   #include "DepositSlot.h" // DepositSlot class definiton
4
5   // indicates whether envelope was received (always returns true,
6   // because this is only a software simulation of a real deposit slot)
7   bool DepositSlot::isEnvelopeReceived() const
8   {
9      return true; // deposit envelope was received
10  } // end function isEnvelopeReceived
```

Fig. 26.23 | DepositSlot class member-function definition.

Recall from the requirements specification that the ATM allows the user up to two minutes to insert an envelope. The current version of member function isEnvelope-Received simply returns true immediately (line 9 of Fig. 26.23), because this is only a software simulation, and we assume that the user has inserted an envelope within the required time frame. If an actual hardware deposit slot were connected to our system, member function isEnvelopeReceived might be implemented to wait for a maximum of two minutes to receive a signal from the hardware deposit slot indicating that the user has indeed inserted a deposit envelope. If isEnvelopeReceived were to receive such a signal within two minutes, the member function would return true. If two minutes elapsed and the member function still had not received a signal, then the member function would return false.

26.4.6 Class Account

Class Account (Figs. 26.24–26.25) represents a bank account. Lines 9–15 in the class definition (Fig. 26.24) contain function prototypes for the class's constructor and six member functions, which we discuss shortly. Each Account has four attributes (modeled in Fig. 26.11)—accountNumber, pin, availableBalance and totalBalance. Lines 17–20 implement these attributes as private data members. Data member availableBalance represents the amount of funds available for withdrawal. Data member totalBalance represents the amount of funds available, plus the amount of deposited funds still pending confirmation or clearance.

```cpp
1   // Account.h
2   // Account class definition. Represents a bank account.
3   #ifndef ACCOUNT_H
4   #define ACCOUNT_H
5
6   class Account
7   {
8   public:
9      Account( int, int, double, double ); // constructor sets attributes
10     bool validatePIN( int ) const; // is user-specified PIN correct?
11     double getAvailableBalance() const; // returns available balance
12     double getTotalBalance() const; // returns total balance
13     void credit( double ); // adds an amount to the Account balance
14     void debit( double ); // subtracts an amount from the Account balance
15     int getAccountNumber() const; // returns account number
16  private:
17     int accountNumber; // account number
18     int pin; // PIN for authentication
19     double availableBalance; // funds available for withdrawal
20     double totalBalance; // funds available + funds waiting to clear
21  }; // end class Account
22
23  #endif // ACCOUNT_H
```

Fig. 26.24 | Account class definition.

Account Class Member-Function Definitions
Figure 26.25 presents the definitions of class Account's member functions. The class's constructor (lines 6–14) takes an account number, the PIN established for the account, the initial available balance and the initial total balance as arguments. Lines 8–11 assign these values to the class's data members using member initializers.

Member function validatePIN (lines 17–23) determines whether a user-specified PIN (i.e., parameter userPIN) matches the PIN associated with the account (i.e., data member pin). Recall that we modeled this member function's parameter userPIN in the UML class diagram of Fig. 25.19. If the two PINs match, the member function returns true (line 20); otherwise, it returns false (line 22).

Member functions getAvailableBalance (lines 26–29) and getTotalBalance (lines 32–35) are *get* functions that return the values of double data members availableBalance and totalBalance, respectively.

Member function `credit` (lines 38–41) adds an amount of money (i.e., parameter `amount`) to an `Account` as part of a deposit transaction. Note that this member function adds the `amount` only to data member `totalBalance` (line 40). The money credited to an account during a deposit does not become available immediately, so we modify only the total balance. We assume that the bank updates the available balance appropriately at a later time. Our implementation of class `Account` includes only member functions required for carrying out ATM transactions. Therefore, we omit the member functions that some other bank system would invoke to add to data member `availableBalance` (to confirm a deposit) or subtract from data member `totalBalance` (to reject a deposit).

```cpp
 1  // Account.cpp
 2  // Member-function definitions for class Account.
 3  #include "Account.h" // Account class definition
 4
 5  // Account constructor initializes attributes
 6  Account::Account( int theAccountNumber, int thePIN,
 7     double theAvailableBalance, double theTotalBalance )
 8     : accountNumber( theAccountNumber ),
 9       pin( thePIN ),
10       availableBalance( theAvailableBalance ),
11       totalBalance( theTotalBalance )
12  {
13     // empty body
14  } // end Account constructor
15
16  // determines whether a user-specified PIN matches PIN in Account
17  bool Account::validatePIN( int userPIN ) const
18  {
19     if ( userPIN == pin )
20        return true;
21     else
22        return false;
23  } // end function validatePIN
24
25  // returns available balance
26  double Account::getAvailableBalance() const
27  {
28     return availableBalance;
29  } // end function getAvailableBalance
30
31  // returns the total balance
32  double Account::getTotalBalance() const
33  {
34     return totalBalance;
35  } // end function getTotalBalance
36
37  // credits an amount to the account
38  void Account::credit( double amount )
39  {
40     totalBalance += amount; // add to total balance
41  } // end function credit
```

Fig. 26.25 | Account class member-function definitions. (Part 1 of 2.)

```
42
43   // debits an amount from the account
44   void Account::debit( double amount )
45   {
46      availableBalance -= amount; // subtract from available balance
47      totalBalance -= amount; // subtract from total balance
48   } // end function debit
49
50   // returns account number
51   int Account::getAccountNumber() const
52   {
53      return accountNumber;
54   } // end function getAccountNumber
```

Fig. 26.25 | Account class member-function definitions. (Part 2 of 2.)

Member function debit (lines 44–48) subtracts an amount of money (i.e., parameter amount) from an Account as part of a withdrawal transaction. This member function subtracts the amount from both data member availableBalance (line 46) and data member totalBalance (line 47), because a withdrawal affects both measures of an account balance.

Member function getAccountNumber (lines 51–54) provides access to an Account's accountNumber. We include this member function in our implementation so that a client of the class (i.e., BankDatabase) can identify a particular Account. For example, BankDatabase contains many Account objects, and it can invoke this member function on each of its Account objects to locate the one with a specific account number.

26.4.7 Class BankDatabase

Class BankDatabase (Figs. 26.26–26.27) models the bank's database with which the ATM interacts to access and modify a user's account information. The class definition (Fig. 26.26) declares function prototypes for the class's constructor and several member functions. We discuss these momentarily. The class definition also declares the BankDatabase's data members. We determine one data member for class BankDatabase based on its composition relationship with class Account. Recall from Fig. 26.10 that a BankDatabase is composed of zero or more objects of class Account. Line 24 of Fig. 26.26 implements data member accounts—a vector of Account objects—to implement this composition relationship. Lines 6–7 allow us to use vector in this file. Line 27 contains the function prototype for a private utility function getAccount that allows the member functions of the class to obtain a pointer to a specific Account in the accounts vector.

```
1   // BankDatabase.h
2   // BankDatabase class definition. Represents the bank's database.
3   #ifndef BANK_DATABASE_H
4   #define BANK_DATABASE_H
5
6   #include <vector> // class uses vector to store Account objects
7   using namespace std;
```

Fig. 26.26 | BankDatabase class definition. (Part 1 of 2.)

```
8
9    #include "Account.h" // Account class definition
10
11   class BankDatabase
12   {
13   public:
14      BankDatabase(); // constructor initializes accounts
15
16      // determine whether account number and PIN match those of an Account
17      bool authenticateUser( int, int ); // returns true if Account authentic
18
19      double getAvailableBalance( int ); // get an available balance
20      double getTotalBalance( int ); // get an Account's total balance
21      void credit( int, double ); // add amount to Account balance
22      void debit( int, double ); // subtract amount from Account balance
23   private:
24      vector< Account > accounts; // vector of the bank's Accounts
25
26      // private utility function
27      Account * getAccount( int ); // get pointer to Account object
28   }; // end class BankDatabase
29
30   #endif // BANK_DATABASE_H
```

Fig. 26.26 | BankDatabase class definition. (Part 2 of 2.)

BankDatabase *Class Member-Function Definitions*
Figure 26.27 contains the member-function definitions for class BankDatabase. We implement the class with a default constructor (lines 6–15) that adds Account objects to data member accounts. For the sake of testing the system, we create two new Account objects with test data (lines 9–10), then add them to the end of the vector (lines 13–14). The Account constructor has four parameters—the account number, the PIN assigned to the account, the initial available balance and the initial total balance.

```
1    // BankDatabase.cpp
2    // Member-function definitions for class BankDatabase.
3    #include "BankDatabase.h" // BankDatabase class definition
4
5    // BankDatabase default constructor initializes accounts
6    BankDatabase::BankDatabase()
7    {
8       // create two Account objects for testing
9       Account account1( 12345, 54321, 1000.0, 1200.0 );
10      Account account2( 98765, 56789, 200.0, 200.0 );
11
12      // add the Account objects to the vector accounts
13      accounts.push_back( account1 ); // add account1 to end of vector
14      accounts.push_back( account2 ); // add account2 to end of vector
15   } // end BankDatabase default constructor
16
```

Fig. 26.27 | BankDatabase class member-function definitions. (Part 1 of 3.)

```
17   // retrieve Account object containing specified account number
18   Account * BankDatabase::getAccount( int accountNumber )
19   {
20      // loop through accounts searching for matching account number
21      for ( size_t i = 0; i < accounts.size(); i++ )
22      {
23         // return current account if match found
24         if ( accounts[ i ].getAccountNumber() == accountNumber )
25            return &accounts[ i ];
26      } // end for
27
28      return NULL; // if no matching account was found, return NULL
29   } // end function getAccount
30
31   // determine whether user-specified account number and PIN match
32   // those of an account in the database
33   bool BankDatabase::authenticateUser( int userAccountNumber,
34      int userPIN )
35   {
36      // attempt to retrieve the account with the account number
37      Account * const userAccountPtr = getAccount( userAccountNumber );
38
39      // if account exists, return result of Account function validatePIN
40      if ( userAccountPtr != NULL )
41         return userAccountPtr->validatePIN( userPIN );
42      else
43         return false; // account number not found, so return false
44   } // end function authenticateUser
45
46   // return available balance of Account with specified account number
47   double BankDatabase::getAvailableBalance( int userAccountNumber )
48   {
49      Account * const userAccountPtr = getAccount( userAccountNumber );
50      return userAccountPtr->getAvailableBalance();
51   } // end function getAvailableBalance
52
53   // return total balance of Account with specified account number
54   double BankDatabase::getTotalBalance( int userAccountNumber )
55   {
56      Account * const userAccountPtr = getAccount( userAccountNumber );
57      return userAccountPtr->getTotalBalance();
58   } // end function getTotalBalance
59
60   // credit an amount to Account with specified account number
61   void BankDatabase::credit( int userAccountNumber, double amount )
62   {
63      Account * const userAccountPtr = getAccount( userAccountNumber );
64      userAccountPtr->credit( amount );
65   } // end function credit
66
67   // debit an amount from Account with specified account number
68   void BankDatabase::debit( int userAccountNumber, double amount )
69   {
```

Fig. 26.27 | BankDatabase class member-function definitions. (Part 2 of 3.)

```
70      Account * const userAccountPtr = getAccount( userAccountNumber );
71      userAccountPtr->debit( amount );
72  } // end function debit
```

Fig. 26.27 | BankDatabase class member-function definitions. (Part 3 of 3.)

Recall that class BankDatabase serves as an intermediary between class ATM and the actual Account objects that contain users' account information. Thus, the member functions of class BankDatabase do nothing more than invoke the corresponding member functions of the Account object belonging to the current ATM user.

We include *private utility function* getAccount (lines 18–29) to allow the Bank-Database to obtain a pointer to a particular Account within vector accounts. To locate the user's Account, the BankDatabase compares the value returned by member function getAccountNumber for each element of accounts to a specified account number until it finds a match. Lines 21–26 traverse the accounts vector. If the account number of the current Account (i.e., accounts[i]) equals the value of parameter accountNumber, the member function immediately returns the address of the current Account (i.e., a pointer to the current Account). If no account has the given account number, then line 28 returns NULL. Note that this member function must return a pointer, as opposed to a reference, because there is the possibility that the return value could be NULL—*a reference cannot be NULL, but a pointer can.*

Note that vector function size (invoked in the loop-continuation condition in line 21) returns the number of elements in a vector as a value of type size_t (which is usually unsigned int). As a result, we declare the control variable i to be of type size_t, too. On some compilers, declaring i as an int would cause the compiler to issue a warning message, because the loop-continuation condition would compare a signed value (i.e., an int) and an unsigned value (i.e., a value of type size_t).

Member function authenticateUser (lines 33–44) proves or disproves the an ATM user's identity. This function takes a user-specified account number and user-specified PIN as arguments and indicates whether they match the account number and PIN of an Account in the database. Line 37 calls utility function getAccount, which returns either a pointer to an Account with userAccountNumber as its account number or NULL to indicate that userAccountNumber is invalid. We declare userAccountPtr to be a const pointer because, once the member function aims this pointer at the user's Account, the pointer should not change. If getAccount returns a pointer to an Account object, line 41 returns the bool value returned by that object's validatePIN member function. BankDatabase's authenticateUser member function does not perform the PIN comparison itself—rather, it forwards userPIN to the Account object's validatePIN member function to do so. The value returned by Account member function validatePIN indicates whether the user-specified PIN matches the PIN of the user's Account, so member function authenticateUser simply returns this value to the client of the class (i.e., ATM).

BankDatabase trusts the ATM to invoke member function authenticateUser and receive a return value of true before allowing the user to perform transactions. BankDatabase also trusts that each Transaction object created by the ATM contains the valid account number of the current authenticated user and that this is the account number passed to the remaining BankDatabase member functions as argument userAccountNumber.

Member functions getAvailableBalance (lines 47–51), getTotalBalance (lines 54–58), credit (lines 61–65) and debit (lines 68–72) therefore simply retrieve a pointer to the user's Account object with utility function getAccount, then use this pointer to invoke the appropriate Account member function on the user's Account object. We know that the calls to getAccount within these member functions will never return NULL, because user-AccountNumber must refer to an existing Account. Note that getAvailableBalance and getTotalBalance return the values returned by the corresponding Account member functions. Also, credit and debit simply redirect parameter amount to the Account member functions they invoke.

26.4.8 Class Transaction

Class Transaction (Figs. 26.28–26.29) is an *abstract base class* that represents the notion of an ATM transaction. It contains the common features of derived classes BalanceInquiry, Withdrawal and Deposit. Figure 26.28 expands upon the Transaction header file first developed in Section 26.3. Lines 13, 17–19 and 22 contain function prototypes for the class's constructor and four member functions, which we discuss shortly. Line 15 defines a *virtual destructor* with an empty body—this makes all derived-class destructors virtual (even those defined implicitly by the compiler) and ensures that dynamically allocated derived-class objects get destroyed properly when they are deleted via a base-class pointer. Lines 24–26 declare the class's private data members. Recall from the class diagram of Fig. 26.11 that class Transaction contains an attribute accountNumber (implemented in line 24) that indicates the account involved in the Transaction. We derive data members screen (line 25) and bankDatabase (line 26) from class Transaction's associations modeled in Fig. 26.10—all transactions require access to the ATM's screen and the bank's database, so we include references to a Screen and a BankDatabase as data members of class Transaction. As you'll soon see, Transaction's constructor initializes these references. The forward declarations in lines 6–7 signify that the header file contains references to objects of classes Screen and BankDatabase, but that the definitions of these classes lie outside the header file.

```
1   // Transaction.h
2   // Transaction abstract base class definition.

33   } // end function getBankDatabase
```

Fig. 26.29 | Transaction class member-function definitions.

Class `Transaction` has a constructor (declared in line 13 of Fig. 26.28 and defined in lines 8–15 of Fig. 26.29) that takes the current user's account number and references to the ATM's screen and the bank's database as arguments. Because `Transaction` is an abstract class, this constructor will never be called directly to instantiate `Transaction` objects. Instead, the constructors of the `Transaction` derived classes will use *base-class initializer syntax* to invoke this constructor.

Class `Transaction` has three `public` *get* functions—`getAccountNumber` (declared in line 17 of Fig. 26.28 and defined in lines 18–21 of Fig. 26.29), `getScreen` (declared in line 18 of Fig. 26.28 and defined in lines 24–27 of Fig. 26.29) and `getBankDatabase` (declared in line 19 of Fig. 26.28 and defined in lines 30–33 of Fig. 26.29). `Transaction` derived classes inherit these member functions from `Transaction` and use them to gain access to class `Transaction`'s `private` data members.

Class `Transaction` also declares a pure `virtual` function `execute` (line 22 of Fig. 26.28). It does not make sense to provide an implementation for this member function, because a generic transaction cannot be executed. Thus, we declare this member function to be a pure `virtual` function and force each `Transaction` derived class to provide its own concrete implementation that executes that particular type of transaction.

26.4.9 Class `BalanceInquiry`

Class `BalanceInquiry` (Figs. 26.30–26.31) derives from abstract base class `Transaction` and represents a balance-inquiry ATM transaction. `BalanceInquiry` does not have any data members of its own, but it inherits `Transaction` data members `accountNumber`, `screen` and `bankDatabase`, which are accessible through `Transaction`'s `public` *get* functions. Line 6 `#includes` the definition of base class `Transaction`. The `BalanceInquiry` constructor (declared in line 11 of Fig. 26.30 and defined in lines 8–13 of Fig. 26.31) takes arguments corresponding to the `Transaction` data members and simply forwards them to `Transaction`'s constructor, using *base-class initializer syntax* (line 10 of Fig. 26.31). Line 12 of Fig. 26.30 contains the function prototype for member function `execute`, which is required to indicate the intention to override the base class's pure `virtual` function of the same name.

```
1   // BalanceInquiry.h
2   // BalanceInquiry class definition. Represents a balance inquiry.
3   #ifndef BALANCE_INQUIRY_H
4   #define BALANCE_INQUIRY_H
5
6   #include "Transaction.h" // Transaction class definition
7
8   class BalanceInquiry : public Transaction
9   {
10  public:
11     BalanceInquiry( int, Screen &, BankDatabase & ); // constructor
12     virtual void execute(); // perform the transaction
13  }; // end class BalanceInquiry
14
15  #endif // BALANCE_INQUIRY_H
```

Fig. 26.30 | `BalanceInquiry` class definition.

```
 1   // BalanceInquiry.cpp
 2   // Member-function definitions for class BalanceInquiry.
 3   #include "BalanceInquiry.h" // BalanceInquiry class definition
 4   #include "Screen.h" // Screen class definition
 5   #include "BankDatabase.h" // BankDatabase class definition
 6
 7   // BalanceInquiry constructor initializes base-class data members
 8   BalanceInquiry:: BalanceInquiry( int userAccountNumber, Screen &atmScreen,
 9      BankDatabase &atmBankDatabase )
10      : Transaction( userAccountNumber, atmScreen, atmBankDatabase )
11   {
12      // empty body
13   } // end BalanceInquiry constructor
14
15   // performs transaction; overrides Transaction's pure virtual function
16   void BalanceInquiry::execute()
17   {
18      // get references to bank database and screen
19      BankDatabase &bankDatabase = getBankDatabase();
20      Screen &screen = getScreen();
21
22      // get the available balance for the current user's Account
23      double availableBalance =
24         bankDatabase.getAvailableBalance( getAccountNumber() );
25
26      // get the total balance for the current user's Account
27      double totalBalance =
28         bankDatabase.getTotalBalance( getAccountNumber() );
29
30      // display the balance information on the screen
31      screen.displayMessageLine( "\nBalance Information:" );
32      screen.displayMessage( " - Available balance: " );
33      screen.displayDollarAmount( availableBalance );
34      screen.displayMessage( "\n - Total balance:      " );
35      screen.displayDollarAmount( totalBalance );
36      screen.displayMessageLine( "" );
37   } // end function execute
```

Fig. 26.31 | `BalanceInquiry` class member-function definitions.

Class `BalanceInquiry` overrides `Transaction`'s pure `virtual` function `execute` to provide a concrete implementation (lines 16–37 of Fig. 26.31) that performs the steps involved in a balance inquiry. Lines 19–20 get references to the bank database and the ATM's screen by invoking member functions inherited from base class `Transaction`. Lines 23–24 retrieve the available balance of the account involved by invoking member function `getAvailableBalance` of `bankDatabase`. Line 24 uses inherited member function `getAccountNumber` to get the account number of the current user, which it then passes to `getAvailableBalance`. Lines 27–28 retrieve the total balance of the current user's account. Lines 31–36 display the balance information on the ATM's screen. Recall that `displayDollarAmount` takes a `double` argument and outputs it to the screen formatted as a dollar amount. For example, if a user's `availableBalance` is `700.5`, line 33 outputs `$700.50`. Line 36 inserts a blank line of output to separate the balance information

from subsequent output (i.e., the main menu repeated by class ATM after executing the BalanceInquiry).

26.4.10 Class Withdrawal

Class Withdrawal (Figs. 26.32–26.33) derives from Transaction and represents a withdrawal ATM transaction. Figure 26.32 expands upon the header file for this class developed in Fig. 26.13. Class Withdrawal has a constructor and one member function execute, which we discuss shortly. Recall from the class diagram of Fig. 26.11 that class Withdrawal has one attribute, amount, which line 16 implements as an int data member. Figure 26.10 models associations between class Withdrawal and classes Keypad and CashDispenser, for which lines 17–18 implement references keypad and cashDispenser, respectively. Line 19 is the function prototype of a private utility function that we soon discuss.

```cpp
1   // Withdrawal.h
2   // Withdrawal class definition. Represents a withdrawal transaction.
3   #ifndef WITHDRAWAL_H
4   #define WITHDRAWAL_H
5
6   #include "Transaction.h" // Transaction class definition
7   class Keypad; // forward declaration of class Keypad
8   class CashDispenser; // forward declaration of class CashDispenser
9
10  class Withdrawal : public Transaction
11  {
12  public:
13     Withdrawal( int, Screen &, BankDatabase &, Keypad &, CashDispenser & );
14     virtual void execute(); // perform the transaction
15  private:
16     int amount; // amount to withdraw
17     Keypad &keypad; // reference to ATM's keypad
18     CashDispenser &cashDispenser; // reference to ATM's cash dispenser
19     int displayMenuOfAmounts() const; // display the withdrawal menu
20  }; // end class Withdrawal
21
22  #endif // WITHDRAWAL_H
```

Fig. 26.32 | Withdrawal class definition.

Withdrawal Class Member-Function Definitions

Figure 26.33 contains the member-function definitions for class Withdrawal. Line 3 #includes the class's definition, and lines 4–7 #include the definitions of the other classes used in Withdrawal's member functions. Line 11 declares a global constant corresponding to the cancel option on the withdrawal menu. We'll soon discuss how the class uses this constant.

```cpp
1   // Withdrawal.cpp
2   // Member-function definitions for class Withdrawal.
3   #include "Withdrawal.h" // Withdrawal class definition
```

Fig. 26.33 | Withdrawal class member-function definitions. (Part 1 of 4.)

```
 4   #include "Screen.h" // Screen class definition
 5   #include "BankDatabase.h" // BankDatabase class definition
 6   #include "Keypad.h" // Keypad class definition
 7   #include "CashDispenser.h" // CashDispenser class definition
 8
 9   // global constant that corresponds to menu option to cancel
10   static const int CANCELED = 6;
11
12   // Withdrawal constructor initialize class's data members
13   Withdrawal::Withdrawal( int userAccountNumber, Screen &atmScreen,
14      BankDatabase &atmBankDatabase, Keypad &atmKeypad,
15      CashDispenser &atmCashDispenser )
16      : Transaction( userAccountNumber, atmScreen, atmBankDatabase ),
17        keypad( atmKeypad ), cashDispenser( atmCashDispenser )
18   {
19      // empty body
20   } // end Withdrawal constructor
21
22   // perform transaction; overrides Transaction's pure virtual function
23   void Withdrawal::execute()
24   {
25      bool cashDispensed = false; // cash was not dispensed yet
26      bool transactionCanceled = false; // transaction was not canceled yet
27
28      // get references to bank database and screen
29      BankDatabase &bankDatabase = getBankDatabase();
30      Screen &screen = getScreen();
31
32      // loop until cash is dispensed or the user cancels
33      do
34      {
35         // obtain the chosen withdrawal amount from the user
36         int selection = displayMenuOfAmounts();
37
38         // check whether user chose a withdrawal amount or canceled
39         if ( selection != CANCELED )
40         {
41            amount = selection; // set amount to the selected dollar amount
42
43            // get available balance of account involved
44            double availableBalance =
45               bankDatabase.getAvailableBalance( getAccountNumber() );
46
47            // check whether the user has enough money in the account
48            if ( amount <= availableBalance )
49            {
50               // check whether the cash dispenser has enough money
51               if ( cashDispenser.isSufficientCashAvailable( amount ) )
52               {
53                  // update the account involved to reflect withdrawal
54                  bankDatabase.debit( getAccountNumber(), amount );
55
56                  cashDispenser.dispenseCash( amount ); // dispense cash
```

Fig. 26.33 | Withdrawal class member-function definitions. (Part 2 of 4.)

```
57                     cashDispensed = true; // cash was dispensed
58
59                     // instruct user to take cash
60                     screen.displayMessageLine(
61                         "\nPlease take your cash from the cash dispenser." );
62                 } // end if
63                 else // cash dispenser does not have enough cash
64                     screen.displayMessageLine(
65                         "\nInsufficient cash available in the ATM."
66                         "\n\nPlease choose a smaller amount." );
67             } // end if
68             else // not enough money available in user's account
69             {
70                 screen.displayMessageLine(
71                     "\nInsufficient funds in your account."
72                     "\n\nPlease choose a smaller amount." );
73             } // end else
74         } // end if
75         else // user chose cancel menu option
76         {
77             screen.displayMessageLine( "\nCanceling transaction..." );
78             transactionCanceled = true; // user canceled the transaction
79         } // end else
80     } while ( !cashDispensed && !transactionCanceled ); // end do...while
81 } // end function execute
82
83 // display a menu of withdrawal amounts and the option to cancel;
84 // return the chosen amount or 0 if the user chooses to cancel
85 int Withdrawal::displayMenuOfAmounts() const
86 {
87     int userChoice = 0; // local variable to store return value
88
89     Screen &screen = getScreen(); // get screen reference
90
91     // array of amounts to correspond to menu numbers
92     int amounts[] = { 0, 20, 40, 60, 100, 200 };
93

```
109          // determine how to proceed based on the input value
110          switch ( input )
111          {
112             case 1: // if the user chose a withdrawal amount
113             case 2: // (i.e., chose option 1, 2, 3, 4 or 5), return the
114             case 3: // corresponding amount from amounts array
115             case 4:
116             case 5:
117                userChoice = amounts[ input ]; // save user's choice
118                break;
119             case CANCELED: // the user chose to cancel
120                userChoice = CANCELED; // save user's choice
121                break;
122             default: // the user did not enter a value from 1-6
123                screen.displayMessageLine(
124                   "\nIvalid selection. Try again." );
125          } // end switch
126       } // end while
127
128       return userChoice; // return withdrawal amount or CANCELED
129    } // end function displayMenuOfAmounts
```

Fig. 26.33 | Withdrawal class member-function definitions. (Part 4 of 4.)

Class Withdrawal's constructor (defined in lines 13–20 of Fig. 26.33) has five param-
eters. It uses a base-class initializer in line 16 to pass parameters userAccountNumber, atm-
Screen and atmBankDatabase to base class Transaction's constructor to set the data
members that Withdrawal inherits from Transaction. The constructor also takes refer-
ences atmKeypad and atmCashDispenser as parameters and assigns them to reference data
members keypad and cashDispenser using member initializers (line 17).

Class Withdrawal overrides Transaction's pure virtual function execute with a
concrete implementation (lines 23–81) that performs the steps involved in a withdrawal.
Line 25 declares and initializes a local bool variable cashDispensed. This variable indi-
cates whether cash has been dispensed (i.e., whether the transaction has completed success-
fully) and is initially false. Line 26 declares and initializes to false a bool variable
transactionCanceled that indicates whether the transaction has been canceled by the
user. Lines 29–30 get references to the bank database and the ATM's screen by invoking
member functions inherited from base class Transaction.

Lines 33–80 contain a do...while statement that executes its body until cash is dis-
pensed (i.e., until cashDispensed becomes true) or until the user chooses to cancel (i.e.,
until transactionCanceled becomes true). This loop continuously returns the user to
the start of the transaction if an error occurs (i.e., the requested withdrawal amount is
greater than the user's available balance or greater than the amount of cash in the cash dis-
penser). Line 36 displays a menu of withdrawal amounts and obtains a user selection by
calling private utility function displayMenuOfAmounts (defined in lines 85–129). This
function displays the menu of amounts and returns either an int withdrawal amount or
the int constant CANCELED to indicate that the user has chosen to cancel the transaction.

Member function displayMenuOfAmounts (lines 85–129) first declares local variable
userChoice (initially 0) to store the value that the member function will return (line 87).

Line 89 gets a reference to the screen by calling member function `getScreen` inherited from base class `Transaction`. Line 92 declares an integer array of withdrawal amounts that correspond to the amounts displayed in the withdrawal menu. We ignore the first element in the array (index 0) because the menu has no option 0. The `while` statement in lines 95–126 repeats until `userChoice` takes on a value other than 0. We'll see shortly that this occurs when the user makes a valid selection from the menu. Lines 98–105 display the withdrawal menu on the screen and prompt the user to enter a choice. Line 107 obtains integer `input` through the keypad. The `switch` statement in lines 110–125 determines how to proceed based on the user's input. If the user selects a number between 1 and 5, line 117 sets `userChoice` to the value of the element in `amounts` at index `input`. For example, if the user enters 3 to withdraw $60, line 117 sets `userChoice` to the value of `amounts[ 3 ]` (i.e., 60). Line 118 terminates the `switch`. Variable `userChoice` no longer equals 0, so the `while` in lines 95–126 terminates and line 128 returns `userChoice`. If the user selects the cancel menu option, lines 120–121 execute, setting `userChoice` to `CANCELED` and causing the member function to return this value. If the user does not enter a valid menu selection, lines 123–124 display an error message and the user is returned to the withdrawal menu.

The `if` statement in line 39 in member function `execute` determines whether the user has selected a withdrawal amount or chosen to cancel. If the user cancels, lines 77–78 execute to display an appropriate message to the user and set `transactionCanceled` to `true`. This causes the loop-continuation test in line 80 to fail and control to return to the calling member function (i.e., ATM member function `performTransactions`). If the user has chosen a withdrawal amount, line 41 assigns local variable `selection` to data member `amount`. Lines 44–45 retrieve the available balance of the current user's `Account` and store it in a local `double` variable `availableBalance`. Next, the `if` statement in line 48 determines whether the selected amount is less than or equal to the user's available balance. If it isn't, lines 70–72 display an appropriate error message. Control then continues to the end of the `do...while`, and the loop repeats because both `cashDispensed` and `transactionCanceled` are still `false`. If the user's balance is high enough, the `if` statement in line 51 determines whether the cash dispenser has enough money to satisfy the withdrawal request by invoking the `cashDispenser`'s `isSufficientCashAvailable` member function. If this member function returns `false`, lines 64–66 display an appropriate error message and the `do...while` repeats. If sufficient cash is available, then the requirements for the withdrawal are satisfied, and line 54 debits `amount` from the user's account in the database. Lines 56–57 then instruct the cash dispenser to dispense the cash to the user and set `cashDispensed` to `true`. Finally, lines 60–61 display a message to the user that cash has been dispensed. Because `cashDispensed` is now `true`, control continues after the `do...while`. No additional statements appear below the loop, so the member function returns control to class `ATM`.

In the function calls in lines 64–66 and lines 70–72, we divide the argument to `Screen` member function `displayMessageLine` into two string literals, each placed on a separate line in the program. We do so because each argument is too long to fit on a single line. *C++ concatenates (i.e., combines) string literals adjacent to each other, even if they are on separate lines.* For example, if you write `"Happy " "Birthday"` in a program, C++ will view these two adjacent string literals as the single string literal `"Happy Birthday"`. As a result, when lines 64–66 execute, `displayMessageLine` receives a single `string` as a parameter, even though the argument in the function call appears as two string literals.

26.4.11 Class Deposit

Class Deposit (Figs. 26.34–26.35) derives from Transaction and represents a deposit ATM transaction. Figure 26.34 contains the Deposit class definition. Like derived classes BalanceInquiry and Withdrawal, Deposit declares a constructor (line 13) and member function execute (line 14)—we discuss these momentarily. Recall from the class diagram of Fig. 26.11 that class Deposit has one attribute amount, which line 16 implements as an int data member. Lines 17–18 create reference data members keypad and depositSlot that implement the associations between class Deposit and classes Keypad and Deposit-Slot modeled in Fig. 26.10. Line 19 contains the function prototype for a private utility function promptForDepositAmount that we'll discuss shortly.

```
1   // Deposit.h
2   // Deposit class definition. Represents a deposit transaction.
3   #ifndef DEPOSIT_H
4   #define DEPOSIT_H
5
6   #include "Transaction.h" // Transaction class definition
7   class Keypad; // forward declaration of class Keypad
8   class DepositSlot; // forward declaration of class DepositSlot
9
10  class Deposit : public Transaction
11  {
12  public:
13     Deposit( int, Screen &, BankDatabase &, Keypad &, DepositSlot & );
14     virtual void execute(); // perform the transaction
15  private:
16     double amount; // amount to deposit
17     Keypad &keypad; // reference to ATM's keypad
18     DepositSlot &depositSlot; // reference to ATM's deposit slot
19     double promptForDepositAmount() const; // get deposit amount from user
20  }; // end class Deposit
21
22  #endif // DEPOSIT_H
```

Fig. 26.34 | Deposit class definition.

Deposit Class Member-Function Definitions

Figure 26.35 presents the Deposit class implementation. Line 3 #includes the Deposit class definition, and lines 4–7 #include the class definitions of the other classes used in Deposit's member functions. Line 9 declares a constant CANCELED that corresponds to the value a user enters to cancel a deposit. We'll soon discuss how the class uses this constant.

```
1   // Deposit.cpp
2   // Member-function definitions for class Deposit.
3   #include "Deposit.h" // Deposit class definition
4   #include "Screen.h" // Screen class definition
5   #include "BankDatabase.h" // BankDatabase class definition
6   #include "Keypad.h" // Keypad class definition
```

Fig. 26.35 | Deposit class member-function definitions. (Part 1 of 3.)

```cpp
 7   #include "DepositSlot.h" // DepositSlot class definition
 8
 9   static const int CANCELED = 0; // constant representing cancel option
10
11   // Deposit constructor initializes class's data members
12   Deposit::Deposit( int userAccountNumber, Screen &atmScreen,
13      BankDatabase &atmBankDatabase, Keypad &atmKeypad,
14      DepositSlot &atmDepositSlot )
15      : Transaction( userAccountNumber, atmScreen, atmBankDatabase ),
16        keypad( atmKeypad ), depositSlot( atmDepositSlot )
17   {
18      // empty body
19   } // end Deposit constructor
20
21   // performs transaction; overrides Transaction's pure virtual function
22   void Deposit::execute()
23   {
24      BankDatabase &bankDatabase = getBankDatabase(); // get reference
25      Screen &screen = getScreen(); // get reference
26
27      amount = promptForDepositAmount(); // get deposit amount from user
28
29      // check whether user entered a deposit amount or canceled
30      if ( amount != CANCELED )
31      {
32         // request deposit envelope containing specified amount
33         screen.displayMessage(
34            "\nPlease insert a deposit envelope containing " );
35         screen.displayDollarAmount( amount );
36         screen.displayMessageLine( " in the deposit slot." );
37
38         // receive deposit envelope
39         bool envelopeReceived = depositSlot.isEnvelopeReceived();
40
41         // check whether deposit envelope was received
42         if ( envelopeReceived )
43         {
44            screen.displayMessageLine( "\nYour envelope has been received."
45               "\nNOTE: The money deposited will not be available until we"
46               "\nverify the amount of any enclosed cash, and any enclosed "
47               "checks clear." );
48
49            // credit account to reflect the deposit
50            bankDatabase.credit( getAccountNumber(), amount );
51         } // end if
52         else // deposit envelope not received
53         {
54            screen.displayMessageLine( "\nYou did not insert an "
55               "envelope, so the ATM has canceled your transaction." );
56         } // end else
57      } // end if
58      else // user canceled instead of entering amount
59      {
```

Fig. 26.35 | Deposit class member-function definitions. (Part 2 of 3.)

```
60            screen.displayMessageLine( "\nCanceling transaction..." );
61      } // end else
62   } // end function execute
63
64   // prompt user to enter a deposit amount in cents
65   double Deposit::promptForDepositAmount() const
66   {
67      Screen &screen = getScreen(); // get reference to screen
68
69      // display the prompt and receive input
70      screen.displayMessage( "\nPlease enter a deposit amount in "
71         "CENTS (or 0 to cancel): " );
72      int input = keypad.getInput(); // receive input of deposit amount
73
74      // check whether the user canceled or entered a valid amount
75      if ( input == CANCELED )
76         return CANCELED;
77      else
78      {
79         return static_cast< double >( input ) / 100; // return dollar amount
80      } // end else
81   } // end function promptForDepositAmount
```

Fig. 26.35 | Deposit class member-function definitions. (Part 3 of 3.)

Like class Withdrawal, class Deposit contains a constructor (lines 12–19) that passes three parameters to base class Transaction's constructor using a base-class initializer (line 15). The constructor also has parameters atmKeypad and atmDepositSlot, which it assigns to its corresponding data members (line 16).

Member function execute (lines 22–62) overrides pure virtual function execute in base class Transaction with a concrete implementation that performs the steps required in a deposit transaction. Lines 24–25 get references to the database and the screen. Line 27 prompts the user to enter a deposit amount by invoking private utility function promptForDepositAmount (defined in lines 65–81) and sets data member amount to the value returned. Member function promptForDepositAmount asks the user to enter a deposit amount as an integer number of cents (because the ATM's keypad does not contain a decimal point; this is consistent with many real ATMs) and returns the double value representing the dollar amount to be deposited.

Line 67 in member function promptForDepositAmount gets a reference to the ATM's screen. Lines 70–71 display a message on the screen asking the user to input a deposit amount as a number of cents or "0" to cancel the transaction. Line 72 receives the user's input from the keypad. The if statement in lines 75–80 determines whether the user has entered a real deposit amount or chosen to cancel. If the user chooses to cancel, line 76 returns the constant CANCELED. Otherwise, line 79 returns the deposit amount after converting from the number of cents to a dollar amount by casting input to a double, then dividing by 100. For example, if the user enters 125 as the number of cents, line 79 returns 125.0 divided by 100, or 1.25—125 cents is $1.25.

The if statement in lines 30–61 in member function execute determines whether the user has chosen to cancel the transaction instead of entering a deposit amount. If the user cancels, line 60 displays an appropriate message, and the member function returns. If

the user enters a deposit amount, lines 33–36 instruct the user to insert a deposit envelope with the correct amount. Recall that Screen member function displayDollarAmount outputs a double formatted as a dollar amount.

Line 39 sets a local bool variable to the value returned by depositSlot's isEnvelope-Received member function, indicating whether a deposit envelope has been received. Recall that we coded isEnvelopeReceived (lines 7–10 of Fig. 26.23) to always return true, because we are simulating the functionality of the deposit slot and assume that the user always inserts an envelope. However, we code member function execute of class Deposit to test for the possibility that the user does not insert an envelope—good software engineering demands that programs account for all possible return values. Thus, class Deposit is prepared for future versions of isEnvelopeReceived that could return false. Lines 44–50 execute if the deposit slot receives an envelope. Lines 44–47 display an appropriate message to the user. Line 50 then credits the deposit amount to the user's account in the database. Lines 54–55 will execute if the deposit slot does not receive a deposit envelope. In this case, we display a message to the user stating that the ATM has canceled the transaction. The member function then returns without modifying the user's account.

26.4.12 Test Program ATMCaseStudy.cpp

ATMCaseStudy.cpp (Fig. 26.36) is a simple C++ program that allows us to start, or "turn on," the ATM and test the implementation of our ATM system model. The program's main function (lines 6–11) does nothing more than instantiate a new ATM object named atm (line 8) and invoke its run member function (line 9) to start the ATM.

```
1   // ATMCaseStudy.cpp
2   // Driver program for the ATM case study.
3   #include "ATM.h" // ATM class definition
4
5   // main function creates and runs the ATM
6   int main()
7   {
8      ATM atm; // create an ATM object
9      atm.run(); // tell the ATM to start
10  } // end main
```

Fig. 26.36 │ ATMCaseStudy.cpp starts the ATM system.

26.5 Wrap-Up

In this chapter, you used inheritance to tune the design of the ATM software system, and you fully implemented the ATM in C++. Congratulations on completing the entire ATM case study! We hope you found this experience to be valuable and that it reinforced many of the object-oriented programming concepts that you've learned.

Answers to Self-Review Exercises

26.1   True. The minus sign (–) indicates private visibility. We've mentioned "friendship" as an exception to private visibility. Friendship is discussed in Chapter 9.

26.2   b.

26.3   The design for class `Account` yields the header file in Fig. 26.37.

```
1   // Fig. 26.37: Account.h
2   // Account class definition. Represents a bank account.
3   #ifndef ACCOUNT_H
4   #define ACCOUNT_H
5
6   class Account
7   {
8   public:
9      bool validatePIN( int ); // is user-specified PIN correct?
10     double getAvailableBalance(); // returns available balance
11     double getTotalBalance(); // returns total balance
12     void credit( double ); // adds an amount to the Account
13     void debit( double ); // subtracts an amount from the Account
14  private:
15     int accountNumber; // account number
16     int pin; // PIN for authentication
17     double availableBalance; // funds available for withdrawal
18     double totalBalance; // funds available + funds waiting to clear
19  }; // end class Account
20
21  #endif // ACCOUNT_H
```

Fig. 26.37 | `Account` class header file based on Fig. 26.1 and Fig. 26.2.

26.4   b.

26.5   False. The UML requires that we italicize abstract class names and operation names.

26.6   The design for class `Transaction` yields the header file in Fig. 26.38. In the implementation, a constructor initializes `private` reference attributes `screen` and `bankDatabase` to actual objects, and member functions `getScreen` and `getBankDatabase` access these attributes. These member functions allow classes derived from `Transaction` to access the ATM's screen and interact with the bank's database.

```
1   // Fig. 36.38: Transaction.h
2   // Transaction abstract base class definition.
3   #ifndef TRANSACTION_H
4   #define TRANSACTION_H
5
6   class Screen; // forward declaration of class Screen
7   class BankDatabase; // forward declaration of class BankDatabase
8
9   class Transaction
10  {
11  public:
12     int getAccountNumber(); // return account number
13     Screen &getScreen(); // return reference to screen
14     BankDatabase &getBankDatabase(); // return reference to bank database
```

Fig. 26.38 | `Transaction` class header file based on Fig. 26.10 and Fig. 26.11. (Part 1 of 2.)

```
15
16      // pure virtual function to perform the transaction
17      virtual void execute() = 0; // overridden in derived classes
18   private:
19      int accountNumber; // indicates account involved
20      Screen &screen; // reference to the screen of the ATM
21      BankDatabase &bankDatabase; // reference to the account info database
22   }; // end class Transaction
23
24   #endif // TRANSACTION_H
```

Fig. 26.38 | Transaction class header file based on Fig. 26.10 and Fig. 26.11. (Part 2 of 2.)
